INDEX

Abdomen ; gunshot wounds of, 283 ; puncture for flatulent distention, 654 ; section for purulent peritonitis, 75 ; traumatism (Morton), 260, 267 ; statistics in Kieff, 510 ; tumors, and large heart, 217 ; penetrating wound, 410 ; surgery. general work in, 425 ; massage, constipation treated by, 472.
Abnormality, fœtal, 153.
Abort a felon, how to, 249.
Abortion ; long retention of placenta in (Smith), 348 ; following the use of potassium permanganate, 730.
Abortive treatment, an example of, 412.
Abscess ; of breast, 135 ; of lung, 366 ; of brain, trephining for supposed, 412 ; hepatic, treatment of, 569 ; psoas, evacuation of, 630.
Absorbent canton flannel, 596.
Absorption ; in acute intestinal catarrh, 147 ; of corrosive sublimate by the skin, 185.
Acetanilide, 252 ; or antifebrine, 123.
Acid ; salicylic in food, 251 ; boric, use of, 272 ; oxalic, an emmenagogue, 280 ; salicylic, caution in use of, 339 ; boracic, herrings cured by, 351 ; hydrobromic, as a remedial agent (Anders), 417 ; carbolic, treatment of vomiting, 442 ; hydrochloric, in gastric diseases, 499 ; found in human urine, 558 ; carbolic, inhalations in whooping-cough, 568 ; chromic, pure, 636 ; Cæsarian operation and chronic acid catgut, 569.
Ackley—Biniodide of mercury a germicide, 6.
Acne ; treatment of, 175, 308 ; of the female, hot vaginal douche in, 714.
Aconite ; antidote for, 216 ; poisoning by, 312 ; in neuralgia, 666.
Aconitine in neuralgia, 506.
Acrobats and science, 286.
Acuminated warts, resorcin in, 217.
Acute ; peritonitis, laparotomy in, 109 ; albuminuria, drugs in, 184 ; multiple gangrene of the skin, 218 ; orchitis, pulsatilla in, 220 ; disease in opium habitués, 337 ; pneumonia in utero, 379 ; gastritis, cocaine in, 466 ; fevers, glycerine in treatment of, 474 ; diseases, dangers of high temperature in, 698 ; intestinal obstruction, 780.
Acuteness, olfactory, 222.
Adenoid ; bronchocele, 284 ; growth in the nose, 505.
Adhesive plaster, 569.
Adulteration ; in Paris, 158 ; of food in Spain, 320.
Administration of carbonate of lime in cancerous tumors, 722.
Advantages of cinchonidine, 761.
Advertising, Dr. Squibb on medical, 535.
Affections, intestinal, pomegranate root in, 185.
Agaric in sweating of phthisis, 154.
Aid for the veterinary school, 638.
Ainhum, case of, 649.
Air passages, catheterism of, 463.
A-kawa, resin or lewinin, 279.
Alabama, note from (Sholl), 763.
Albuminuria ; quinine in, 75 ; forms not dangerous to life, 114 ; Bright's disease without, 122 ; action of drugs in, 184 ; renal, milk as prophylactic against, 186 ; Bright's disease without, 566 ; in diabetes, 599 ; of pregnancy, pathology of, 754.
Alcohol ; an anæsthetic, 234 ; in pulmonary phthisis, the rational use of (Huber), 419 ; paralysis, cord and nerves in, 521.
Alcoholism, remedies for, 373.
Alcoholists, mortality of, 181.
Alimentation, artificial, 408.
Aloe leaves for burns, 762.
Amaurosis, quinine, 635.
Amenorrhœa ; pills for, 59 ; prescriptions for, 601.
American ; dentists in Berlin, 607 ; Medical Association and Journal, 631 ; archæology, 633 ; Orthopædic Association, 820 ; Orthopædic Association, members of, 823.
Ames—Forceps and chloroform in labor, 476.
Ammonia ; picrate, in malaria, 341 ; cleaning hair-brushes with, 447.
Amniotic dropsy, prolonged gestation complicated with, 491.
Ammonium picro-nitricum, 602.
Amorphous borate of quiniue, 762.
Amputation ; union by first intention after, 285 ; intra-uterine of forearm, 539 ; of fingers under cocaine, 655.
"Amykos" in catarrh and gonorrhœa, 473.
Amyl, nitrite of, in after-pains, 761.
An epitome of the newer materia medica, 148.
Anæmia ; pernicious, 281 ; entozoa and pernicious, 283 ; among miners, prevalence of, 473 ; postmenstrual, excess of male children when conception occurs at time of, 657.
Anæsthesia, dental, 51 ; of skin by new method, 789.
Anæsthetic ; new local, 88 ; alcohol as, 234 ; chloroform or ether ? 590 ; iodized starch an, 632 ; local, cocaine as, 714.
Anal fisssure, 541 ; treatment of, 187.
Analgesic effects of antipyrin, 785.
Analysis of urine in abdominal tumors, 91.
Anatomy of chorea, pathological, 403.
Anders—The use of hydrobromic acid as a remedial agent, 417.

Aneurism; of aorta, partially consolidated, 116; femoral, cured by instrumental compression, 212; of thoracic aorta, galvano-puncture, 597.
Angeio-spastic angina pectoris (Westbrook), 265.
Angina pectoris, 17, 312; angeiospastic (Westbrook), 265.
Angeioma, of upper extremity, 45.
Ani, pruritus, 665.
Aniline treatment of phthisis, 443, 541.
Ankle joint, compound dislocation of the, 378.
Animals in confinement, diseases of, 286.
Animation suspended, nitro-glycerine in, 220.
Annatto in butter, test of, 377.
Annual report; of the state board of health, 117; of the supervising surgeon general marine hospital service, 213.
Anodyne for dental caries, 667.
Anomalous form of typhoid fever, 507.
Ante-mortem probate of wills, 620.
Anterior nares, plugging the, 217; foreign body in, 329.
Antero-posterior and lateral traction apparatus, 335.
Anthracosis; pulmonum, 623; of both pelvic bones, 786.
Anthrax; transmission of, 94; accidental inoculation of, 126; poison, nature of, 507.
Antidote for arsenic and aconite, 216; to opium, pain as, 700.
Antifebrin in epilepsy, use of (Hare), 744.
Antifebrine, 221, 593; or acetanilide, 123; in typhoid fever, 248, 250; in the royal infirmary, Edinburgh, 412; in the treatment of phthisis, 634.
Antimony poisoning during pregnancy, 157.
Antipyretic in pneumonia, quinine an, 236, 644; medication, 699.
Antipyrin; a hæmostatic, 90; rash produced by, 216; in migraine, 250; in phthisis, 340; physical and chemical properties of, 410; chorea cured by, 602; analgesic effects of, 785; in otalgia nervosa, 786.
Antiseptic; treatment of summer diarrhœa, 139, 244; gonorrhœa (McMullen), 221; salol an, 337; collodion, 411; principle, application of Kirwan, 423; mouth wash, 668; gauze, 753.
Antiseptics in surgery, casualties due to, 723.
Anti-tobacconists, chance for, 605.
Aorta, thoracic, galvano-puncture in aneurism of, 597.
Aortic valves, double disease of (Pepper), 513.
Aphasia, note on, 173.
Apomorphine, 762.
Apoplectic symptoms, treatment of, 783.
Apoplexy, diagnosis of uræmia from, 434.
Apothecaries and prohibition, 158.
Apparatus for preparing dry gypsum-bandages (Wilson), 328; description of an antero-posterior and lateral traction, 335; for gaseous injections into the bowels, 649; for maintaing the lithotomy position, 715; for relief of writers' cramp, 721.
Appendages, uterine, removal of, 282.
Application for keeping hands soft, 782.
Archæology; of artificial limbs, 189; aneurism, 633.
Arctic Surgeon Ambler in memory, 383.
Are they the lost tribes? 382.
Arm and shoulder presentation, 409.
Armless man, feats of, 478.
Arnold—neurasthenia, 257.
Aromatica, rhus, for nocturnal enuresis, 444.
Arsenic; antidote for, 216; in the treatment of malignant tumors, 503.
Arsenical wall papers, 377; eruptions, 636.
Arthritis; gonorrhœal, 220; gonococcus in, 541.
Arthropathia tabica, 144.
Artificial ramus and condyle, 153; limbs, the archæology of, 189; alimentation, 408; feeding, 492; digestion, 657; sulphur water a substitute treatment of Bergeon's treatment of phthisis (Wood), 673; respiration and circulation, 781.
Aseptol, new disinfectant, 121.
Aspergillus nigricans, 338.
Ashby—operation of shortening the round ligaments, 289.
Aphasia, temporary cortical epilepsy with, 395.
Asphyxiated infants, ready method of inducing respiration in (Blackwell), 230.
Aspiration of stomach in drunkenness, 472.
Aspirator in retention of urine, 474.
Asthma; prescription for, 444; galvano-cautery in the treatment of, 529; Bergeon's method in, 636, 718; renal (Fussell), 746.
Ataxia; locomotor, the knee-phenomenon in, 311; spastic, 366; locomotor, with unusual symptoms, 273; herpes associated with, 346.
Athletics, proper field for, 697.
Atrophic orchitis, 280.
Atrophy; progressive muscular, 42; muscular, caused by hydro-myelitis, 275.
Aurium tinnitus, 5, 35, 358, 387.
Auscultation in the diagnosis of pregnancy (Parvin), 232.
Autopsies, pruning shears in, 786.

Babe weighing one pound, 447.
Babies, water, give the, 752.
Bacilli theory, natural history of, 20.
Bacillus; of typhoid fever, 254; of tuberculosis and action of iodoform on, 696.
Backache, cause and cure of, 145.
Bacteria, injection, recent experiments on, 464.
Bacterium termo, treatment of typhus by topical applications, 219.
Baldwin—Diabetes and its relation to carbuncle, 740.
Baked beans, 798.
Balsam of Indian hemp, symptoms after poisoning from, 569.
Bandages, dry gypsum, new apparatus for preparing, 328.
Bauer—Boulimia, caseous pneumonia and death by acute tuberculosis, 133.
Bardwell—Expulsion of tapeworm, 91.
Bartholow—Medical electricity, 565.
Barometer, a whistling, 350.
Basiotribe, Tarnier's, 491.
Belladonna, poisoning by, 312, 439.
Benjamin—the relation between drinking water and typhoid fever, 545.
Benzoin in treatment of ulcers, 123, 244, 665.
Bergeon's treatment of phthisis, method in asthma, 636; artificial sulphur water a substitute for (Wood), 673; by gaseous enemata, 683; method, asthma treated by, 718.
Berlin; American students in, 607; University of, 608.
Bicarbonate of soda in tonsillitis, 123, 444.
Bichloride of mercury, 592; poisoned by, 567.
Bichromate potassium, source of poisoning, 235.
Bimuriate quinine and urea, hypodermatically (Talley), 577.

Biniodide of mercury; a germicide, 6; emenagogue, 316; an antiseptic, 571.
Birdsall — Progressive muscular atrophy, with bulbar symptoms, 42.
Birth, child, treatment of cord after, 754.
Bismuth sub-iodide, new combination, 346.
Black tongue, 312.
Blackwell—Tapeworm expelled by use of turpentine and pumpkin seeds, 92; a ready method of inducing respiration in infants born asphyxiated, 230.
Bladder; rupture of (Parcles), 197; diagnosis of tumors of, 247; male, endoscopy of, 410; stone and cancer of, 474; rupture of, 475, 667; perforation of, 754.
Bleeding from the nose, how to check, 656.
Blistered feet, 636.
Blood; in malaria, 108; in leukæmia, 381; spots on iron, detection of, 415; defibrinated, inhalations of, 601; defibrinated, enemata of, 601.
Bloody spermatic fluid, 797.
Bluebeard, mental alienation of, 79.
Boils, cure of, by injections, 409.
Boldo—Glucine in nervous insomnia, 218.
Bone grafting, 89; screw (Wight), 264.
Boone—Unique penis syringe, 221.
Boracic acid, herrings cured by, 351.
Borax and epilepsy, 56.
Boric acid, 272.
Bottle, how to cut, 670.
Bougies; gelosine in treatment of stricture of the urethra, 242; grooved, treatment of gonorrhœa chronica by, 526.
Boulimia, caseous pneumonia, 133.
Bovine virus, why it fails, 87; virus, uncertainty of, 125.
Bowditch on irregular consultations, 503.
Bowels, apparatus for gaseous injections into the, 649.
Brachial monoplegia complicating enteric fever, 537.
Brain; of epileptics, 164, 171; surgery, 274, 660; gunshot wound of, 284; of a suicide, 365; polyuria and diseases of, 406; trephining for supposed abscess of, 412; sarcoma of, causing hemianopsia, 553; sarcoma of, 553; cyst, with operation, 554; diseases, diagnosis of, 651; disease, obscure case, 747; work, physical basis of, 794.
Breast, carcinoma of, 4.
Breeding, selection in, 733.
Bright's disease, without albuminuria, 122, 566; how comes about, 591; chronic, treatment of (Fussell), 746.
Brinton—On the use of whalebone bougies in the treatment of urethral strictures, 197, 206.
Bronchitis, 667.
Broncho-pneumonia, infectious form of, 471.
Bronchocele, adenoid, 284.
Bromide of ethyl, is chloroform more dangerous than? 105; of nickel in epilepsy, 476.
Brush—The duty of the state to the insane, 321.
Bryant—A manual of operative surgery, 148.
Bundy—Obstetrics in the country, 200.
Bureau of general information, 670.
Burge—Is chloroform in parturition a worse than useless agent? 39.
Burial, Jewish, 28.
Burn, fatal, report of (Dawson), 619.
Burns, treatment of, 600; socotrine aloe leaves for, 762; superficial, remedy for, 797.
Butter; sanitary qualities of artificial (Ludlow), 231; a simple test for, 416.

Cæsarian operation and chromic ácid, 569.
Caffeine in heart disease, 441.
Calculi; intestinal, 251; renal, effects of, 371.
Calculus; the cause of perityphlitis, 412; submaxillary, 463; renal, 623.
Calendula. 47.
Calomel, diuretic action of, 784.
Cancer; intra-ocular, in child, 7; of stomach, sign of, 120; new cure for, 121; intra-ocular, 125; differential diagnosis in the mesentery (Van Bibber), 193; and its treatment, 249; uterine, when to operate in, 344; of cervix uteri (Longaker), 385; uterine, treated by hysterectomy, 403; the curability of, by operation, 411; of the bladder, 474; of stomach, to relieve pain of, 701.
Cancerous growths; removal of, 376; tumors, carbonate of lime as a means of arresting, 722.
Cantharides in hydrophobia, 249.
Canton flannel, absorbent, 596.
Capital punishment, 130; by electricity, 223.
Carbolic acid; pruritus from, 24; treatment of vomiting, 442; inhalations in whooping cough, 568.
Carbonate of lime in cancerous tumors, arresting the growth by, 722.
Carbuncle, diabetes its relation to (Baldwin), 740.
Caruncle, urethral, treatment of, 154.
Carcinoma of breast, 4.
Cardiac incompetency (Pepper), 513.
Care of children, 712.
Caries, dental, anodyne for, 667.
Carlyle on the medical profession, 190.
Cartilages loose in knee-joint, 80.
Cartwright prize, 671.
Cascara sagrada, influence of, 52.
Castor oil, how to give, 602.
Castration and rabies in dogs, 509.
Casualties due to antiseptics in surgery, 723.
Cat, whooping cough in, 752.
Catalepsy; in mother and child, 407; case of, 653.
Cataract induced by the vibrations of tuning-forks, 533.
Catarrh; chronic, turpentine in, 33; acute intestinal, absorption in, 147; "amykos" in, 473; jaundice, treatment of, 594; rational treatment of, 656.
Catharsis produced by hypodermic medication, 443.
Catheter; broken, removed from urethra, 592; a clean double-barreled, 731.
Catgut, reindeer tendons a substitute for, 380.
Catheterism of the air passages, 463.
Cannabinon, haschisch purum and, 442.
Cautery, thermo-, new application of, 697.
Cavity, phthisical, free drainage of, 336.
Cerebellum, pathology of the, 397.
Cerebral; disease, ocular symptoms in acute, 367; origin, right hemianæsthesia of, 408; cortex, focal disease affecting so-called motor region of, 532; localization, 573; and thyroid circulation, relations between, 654; tumor, 719; pneumonia in inebriety, 750.
Cervical; glands, removal of, 39; vertebra, sarcoma substituting sixth, 456.
Cervix uteri, cancer of (Longaker), 385.
Chalk ointment in erysipelas, 221.

Chancre; indurated of the elbow, 217; hard, of the vagina, 217; soft, in middle ear, 309.
Chancres, excision of, 444.
Chancroid, supposed virus of, 459.
Charcot, 606; Lecons sur les maladies du système nerveux, 405.
Chaves—Salicylate of hydrargyrium and its employment in therapeutics, 519.
Chenery—Carcinoma of breast, 4.
Chest, wound of, 681.
Chemical reactions; "dead space" in, 143; properties of antipyrin, 410; constitution and physiological action, connection between, 575.
Child crying in utero, 733.
Child-birth, treatment of cord after, 754.
Children; giving quinine to, 27; papine for, 284; epidemic of exudative tonsillitis in, 625; male, on the excess of, 657; the care of, 712; suppurative pleuritis in, 794.
Chisolm—Intra-ocular cancer in child, 7; rest for painful eyes, is this advice always good? 97.
Chinamen, insane in the United States, 446.
Chinese medical practice in America (Culen), 355.
Chloral; in labor, 669; eye troubles due to, 760.
Chloride of methyl, 89; treatment of neuralgia by, 725; of gold and sodium, 155.
Chlorodyne, 700.
Chloroform; in parturition, 39, 92; more dangerous than bromide of ethyl? 105; death from, 250; and forceps in labor, 476; or ether as anæsthetic? 590.
Chlorosis; pulverized spleen in, 250; sulphur in, 444; obstinate, 668.
Cholera; in Germany, 23; precautions against, 95; during pregnancy, 122; in Buenos Ayres, 126; in Europe, 127; treatment of, 158; most effectual treatment in, 182; ravages in South America, 191; the progress of, 310; collapse of, 378; in South America, 415; the progress of, 470; transmission of, 472; in Buenos Ayres, 511.
Chorea, 155; treatment of, 52, 103; pathological anatomy of, 403; interesting case of, 504; cured by antipyrin, 602; treatment of, 762.
Chromic acid, 636; Cæsarian operation and, 569.
Chronic dysentery, 20; zona, 25; ulcers, treatment of, 183; tropical diarrhœa, treatment of, 217; peritonitis cured by drainage, 219; peritonitis, 301; constipation in childhood treatment of, 368; lead poisoning, 380; dysentery, 381; cocaine poisoning, 412; gastric ulcer, 564; myocarditis (Musser), 643; myelitis, 650; Bright's disease, treatment of (Fussell), 746.
Chunn—Supra-vaginal hysterectomy for fibro-cyst of the uterus, 69, 76.
Cinchona febrifuge in India, 21.
Cinchonidine, advantages of, 761.
Cimicifuga, in treatment of chorea, 52.
Circulation, artificial respiration and, 781.
Circumcision; epilepsy cured by (Sinkler), 229; inoculation of tuberculosis by, 404.
Cirrhosis; of the liver, 623; cure of 508.
Clairvoyant sentenced, 639.
Class-room notes, 662.
Clavicle, excision of entire, 541.
Claybaugh—A case of spontaneous cure of hernia with incidental loss of a testicle, 348.
Climatic treatment of tuberculosis, 378.
Clinical study of glaucoma, 329.
Clitoris, deformity of, 725.
Clubfoot, use of traction in treatment of, 335.
Cobra poison, effect of, 666.
Coca butter for the nails (Phares), 188.
Cocaine; inebriety, 1; in gonorrhœal ophthalmia, 25; in dental anæsthesia, 51; poisoning by, 57, 185, 367; for morphiomania, 84; about, 119; in coryza, 154; in labor, 187; in whooping-cough, 220, 728; and Dobell's solution (Robison), 222; in incoercible vomitings of pregnacy, 249; and previous habits, 279; a poison, 316; peculiar effect of, 436; in acute gastritis, 466; action on the sympathetic, 475; physiological action of, 504; poisoning remedies for, 507; muriate, tetantic convulsions from, 556; amputations of fingers under, 556; a local anæsthetic, 714.
Coca, use of, 223.
Cod-liver oil, 281; pleasant vehicle for, 413; lozenges, 701.
Cohen—On the combination of iron with sodium salicylate in rheumatism and rheumatic affections, 677; ferric salicylate, 798.
Colchicine, 508.
Cold; water in fevers, 246; air, inhalation in typhoid fever, 371; affusion in headache, 441.
Colds taken in cars, 822; treatment of, 783.
Colic, renal, sandalwood oil in, 694.
Colles's fracture, pathology of, 339.
Collodion; antiseptic, 411; coating for pills, 699.

Gastrotomy in Italy, 512.
Gauze, antiseptic, 753.
Genito-urinary, surgeon's association, 604; hyperæsthesia and cystitis, treatment of, 668.
Germany, education of women in, 608.
Gestation prolonged with deformed fœtus, 491.
Gland, the pineal, 314.
Glanders in human subject, 788.
Glands, cervical, removal of, 39.
Glasses, concave, the careless selection of (Risley), 705.
Glaucoma, clinical study of, 329.
Gleet, case of (Rhoads), 444.
Glycerine in treatment of acute fevers, 474.
Glycosuria in nervous diseases, 313.
Goitre; in Himalayas, 83; and cretinism in Peru, 156; extirpation of, 241; treatment of, 283.
Gonococcus in gonorrhœal arthritis, 541.
Gonorrhœa; treatment of, 147, 153; alkaline antiseptic treatment of (McMullen), 221; salicylate of soda in, 444; "amykos" in, 473; chronica, new treatment of, 526.
Gonorrhœal; rheumatism, 23; ophthalmia, cocaine in, 25; arthritis, 220; gonococcus in, 541.
Good advice, 665.
Goodell—Intra-ligamentous ovarian cyst, 9; fibroid tumor of broad ligament, 9; incontinence of urine apparently due to displacement of urethra, 225.

Gosselin, Prof., death of, 734.
Government health reports, 573.
Granular; conjunctivitis, 252; kidney and hæmaturia, 465.
Gravity of diabetes mellitus in early life, 652.
Great men's dishes, 317.
Griffith—Hip-joint disease, 587; Is homœopathy increasing? 797.
Gross—A practical treatise on impotence, sterility, and allied diseases of the male sexual organs, 629.
Growths, horny, of penis, 752.
Gunshot; wounds of abdomen, 283; of brain, 284; epilepsy after, 370; of vertebræ, 411.
Gum acacia in pharmacy, substitute for, 760.
Gut, resection of, 430.
Gynecological; Society of England, 191; and Obstetrical Society of Baltimore, 457, 489.
Gynecology, progress of therapeutics in, 710.
Gypsum bandages, new apparatus for preparing (Wilson), 328.

Hackney—Case of fœtal umbilical hernia, without the true hernial coverings, 509.
Hæmatoma of the ear, treatment of, 346.
Hæmaturia and granular kidney, 465.
Hæmophilia, 27.
Hæmatocolpos, incomplete, 601.
Hæmostatic, antipyrin a, 90.
Hair-brushes cleaned with ammonia, 447.
Hands, inherited congenital deformity of, 537; application for keeping soft, 787.
Hare—The use of antifebrin in epilepsy, 744.
Harem, the physiology of, 209.
Haschisch, purum and cannabinon, 442.
Hatton—Union by first intention after amputation without asepsis, 284; the use of forceps, 636.
Hay-fever; prize essay on, 253, 669; galvanocautery in the treatment of, 529.
Hæmatinuria, attacks of, 88.
Headache; Indian hemp in treatment of, 217; cold affusion in, 441; sick, case of, 455.
Health; effects of petroleum on, 90; local boards of, 512; association, American public, 543; government reports, 573.
Healthy persons, inequality of pupils in, 571.
Hear? in how many ways do we, 469.
Heart; mobility of, 21; malformed, morbus cerulus from, 38; displaced by pleuritic effusion, 108; syphiloma of, 152; and large abdominal tumors, 247; irritable, 278; disease, caffeine in, 441; disease, iodoform in, 444; irritable, of civil life, 624; wound of, 731.
Heebner—Suicide by "Rough on Rats," 187.
Hemianopsia, sarcoma of the brain causing, 553.
Hemianæsthesia, right, of cerebral origin, 408.
Hemorrhage, intra-peritoneal, 114; spinal, 185; uterine, hydrastis in, 346; after paracentesis, 365; abscess, treatment of, 569; post-partum management of, 594; value of, in treatment of wounds, 724.
Hemorrhagica, pachymeningitis, 394.
Hemoptysis, error of diagnosis, 752.
Hepatic hydatid, cure of, by puncture, 372.
Hemorrhoids internal, fluid extract of ergot, 760.
Hereditary syphilis of tongue, 123.
Hernia into umbilical cord, 117; strangulated, radical cure after, 122; spontaneous cure of, (Claybough) 348; fœtal umbilical, (Hackney) 509.
Hermaphroditism unrecognized for 65 years, 593.
Herniotomy in infant, 751.
Heroic method of producing emesis, 731.
Herpes associated with locomotor ataxia, 346.
High license, 662.
Hinsdale—facial spasm and tic-douloureux for which neurectomy and neuro-tension were employed, 166, 169.
Hip-joint disease, 365; perityphlitis followed by, 379; effective treatment of, (Griffith) 587; excision of, 429; examination through rectum, 658; after fever, displacement of, 404.
Hollister—intra-ocular cancer, 125.
Home treatment of mental disease, 698.
Homœopathy increasing? 732; Dr. L. Brunton and, 626; decadence of, 635; is it increasing? (Griffith), 797.
Horny growth on the penis, 375.
Horny growths of penis, 752.
Horwitz—a compend of surgery for students and physicians, 468.
Hospital, new, for Madrid, 447; the Pennsylvania, 606; Charity, of New York, 621.
Hospitals, Paris, a century ago, 382; of Germany, mortality in public lying-in, 465; the work of Continental, 725.
Housemaid's knee, treatment of, 27.
Horwitz—case of sexual hypochondriasis, 745.
Huber, the rational uses of alcohol in pulmonary phthisis, 419.
Hughes—Neuritis plantaris, 629.
Human; body, detecting and locating metallic masses in, 335; to err is, 669.
Humerus, dislocation reduced by right-angle traction, 183.
Hunston—Puerperal convulsions after miscarriage, 541.
Hunter—Persistent pain after abdominal section, 629; the method of, 345.
Hydatid cyst, unusual site of, 276; of liver, 305; hepatic cured by puncture, 372.
Hydrargyrium salicylate in therapeutics (Chaves) 519.
Hydrastis in uterine hemorrhage, 346.
Hydriodate of hyoscine in kidney disease, 597.
Hydrocarbons in hypodermic injection, 89.
Hydro-myelitis, muscular atrophy caused by, 275.
Hydrobromate of quinine, 635.
Hydrobromic acid as a remedial agent (Anders) 417.
Hydrocele, injections of corrosive sublimate, 601.
Hydrochloric acid in necrosed bone abscess, 794.
Hydrofluoric acid in therapeutics, 58.
Hydrocephalus, congenital (Todd) 188.
Hydrochloric acid in gastric diseases, indications for using, 499.
Hydrogen, peroxide of, 636.
Hydrogenium superoxydatum, treatment of diphtheria with, 506.
Hydrophobia, preventive, inoculation for, 30; cantharides in, 249; Pasteur and his experiments on, 342; hydrophobia, 766.
Hydrosalpinx, 206.
Hygiene; of the Talmud to translate and publish the (Klein, Von), 509; museum in Berlin, 671.
Hygienic Congress, 607.
Hyoscine in kidney disease, 436.
Hyperæsthesia, genito-urinary and cystitis, treatment of, 668; retinal, associated with oxaluria (De Schweinitz), 778.
Hypochondriasis, sexual (Horwitz), 745.

Hypnotic, a new, 186 ; suggestion, hysteria cured by, 600.
Hypnotism, medico-legal aspects of, 621.
Hypodermatic use of bimuriate of quinine and urea (Talley), 577.
Hypodermic; injections, hydrocarbons in (A. Good), 186 ; medication, catharsis produced by, 443 ; medication, vaseline for, 443 ; tablets, soluble compressed (Wilson), 517 ; sedative injection, 701 ; medication, novelties in, 764.
Hyoscine hydriodate of, in kidney diseases, 597.
Hysterectomy for myoma, 13 ; supra-vaginal, 69, 76 ; uterine cancer, treated by, 403.
Hysteria, removal of ovaries in, 184 ; cured by hypnotic suggestion, 600.
Hysterical affections, 140 ; paralysis, following dream, 142.
Hysterics and saints, 696.
Hystero-epilepsy, 205.

Ice, in post-partum hemorrhage, 725.
Ichthyol, 55 ; in erysipelas, 250,
Imagination, 29.
Imperforate os-uteri, 143.
Impetigo, turpentine in, 666.
Incandescent lighting, rheostat for utilization of, 622.
Incision in tonsillitis, value of, 372.
Incisor ; tooth, torsion, 282 ; teeth notches which resemble those of syphilis, 784.
Income, average, of the family doctor, 634.
Incompetency, cardiac (Pepper), 513.
Incontinence of urine after labor, 220 ; due to displacement of urethra (Goodell), 235 ; in the female, 506.
Incubation and transmission of epidemic parotitis, 731.
Indian hemp in treatment of headache, 217.
Induction-balance in detecting metallic masses in human body, 335.
Indications for use of nitro-glycerine, 345.
Indurated chancre of the elbow, 218.
Inducing respiration, method of, 761.
Inebriate and lunacy laws, 298 ; jurors, 350.
Inebriety, cocaine, 1 ; traced to intoxication of parents at time of conception (Crothers), 549 ; international Congress of, 671 ; cerebral, pneumonia in, 750.
Inequality of pupils in various diseases, 273 ; in healthy persons, 571.
Infantile constipation, 58 ; disorders, pellétiérine in, 120.
Infant, herniotomy in, 751.
Infants ; born asphyxiated, ready method of inducing respiration in (Blackwell), 230 ; vomiting in young, 284 ; artificial feeding of, 492 ; fractures of long bones in, 732 ; milk for, 785.
Infection, syphilitic, through trousers, 221 ; of wet-nurses by syphilitic sucklings, 377 ; whitlow, 538.
Infectious form of broncbo-pneumonia, 471.
Inflammation of appendix cæci, 46 ; treatment of, 135 ; suppurative, of liver, 298.
Influence; of menstruation on the pulse, 54 ; of tea poisoning on the course of syphilis, 243 ; of disease upon population, 753.
Ingestion of wool, cause of intestinal obstruction, 240.
Ingham—A new departure, 542.
Inglis—Deficiency of the lumbar vertebræ, 92.
Inhalation of cold air in typhoid fever, 371.
Inhalations ; of oxygen in eclampsia, 540 ; of carbolic acid in whooping cough, 568 ; of defibrinated blood, 601.
Inherited phthisis, 409 ; congenital deformity of hands and feet, 537.
Injection ; vaginal, poisoning from, 442 ; of bacteria into the veins, experiments on, 464 ; sedative, hypodermic, 701.
Injections ; the cure of boils by, 409 ; pepsin in tumors, 500 ; corrosive sublimate in hydrocele, 601 ; gaseous, into the bowels, apparatus for, 649.
Injuries and diseases of the urethra (Lydston). 609.
Injurious influences causing deafness (Turnbull), 516.
Injury to shoulder, 540.
Innominate, ligation of, 626.
Inoculation ; against phthisis, 95 ; of anthrax, accidental, 126 ; small-pox, 381 ; of tuberculosis by circumcision, 404 ; a preventive of yellow fever, 536 ; of tuberculosis in Alaska, 657.
Inoculations ; preventive for hydrophobia, 30 ; Pasteur's intensive, 575.
Insane ; private treatment of, 271, 294, 296 ; duty of State to the (Brush), 269, 321 ; caring for the, 381 ; Chinamen in the United States, 446 ; legislation for, 715.
Insanity, self-abuse in, 42.
Insomnia ; nervous, boldo-glucine in, 218 ; functional, treatment of, 720, 728.
Instrument, a new, 234, 714.
Intermittent form of meningitis, 441.
Internal urethrotomy, death following, 725.
Internal hemorrhoids, ergot in, 760.
International Medical Congress, 415, 445, 606, 727 ; on cremation, 446 ; on inebriety, 671.
Intercurrent disease in tubercular patients, 281.
Intestines, vegetable fibres in, 255.
Intestinal lesions produced by drastics, 55 ; catarrh, absorption in, 147 ; affections, pomegranate root in, 185 ; displacement, cause of dyspepsia, 218 ; obstruction, canse of, 240, 281 ; calculi, 251 ; occlusion in, washing out the stomach in, 562 ; obstruction, acute, 780.
Intoxication of parents at time of conception, inebriety traced to (Crothers), 549.
Intra-ligamentous ovarian cyst, 9 ; -abdominal operations, 11 ; -peritoneal hemorrhage, 114 ; -ocular tumor, 330 ; -uterine amputation of forearm, 539 ; -pulmonary medication, 745.
Intubation and tracheotomy in diphtheria, 394 ; deep tubing of the larynx a substitute for, 525 ; of larynx, 792.
Intussusception produced by a tumor growing from mucous membrane, 536.
Iodide of potassium in diphtheria, 402.
Iodine collodion, gangrene from, 27.
Iodized starch an anæsthetic, 632.
Iodoform ointment ; in tubercular meningitis, 24 ; in chronic uterine catarrh, 58 ; in variola and erysipelas, 252 ; pencils, 284 ; poisoning by, 379 ; in heart disease, 444 ; in venereal diseases, 664 ; on the bacillus of tuberculosis and anthrax, 696.
Iodol ; in Belgium, use of, 442 ; in diphtheria, 571.
Irish moss a substitute for gum acacia, 760.
Iron in composition of milk, 282 ; with sodium salicylate in rheumatic affections (Cohen), 677.

Irregular; the, 30; consultations, Dr. Bowditch on, 503.
Irritable heart, 278; of civil life, 624.
Irritability, post-mortem, of muscle, 370.
Irritation, of auditory meatus, prevention of, 314.
Irritations arising from visual apparatus in genesis of neuroses, 522.
Ivy poisoning, treatment of, 667.

Jaborandi leaves, alkaloids of, 52.
Japanese cod-liver oil, 639.
Jaundice; faradization in, 91; catarrhal, treatment of, 594.
Jefferson alumni, 477; Medical College, the old status restored, 799.
Jews of the world, 382.
Johnson—Soothing mixture for consumption, 510.

Kelly—A new leg-holder securing a perfect lithotomy posture without assistants, 747.
Kelly—Par-ovarian cyst, 10; palpation of female uterus, 15.
Kenner—Therapeutical notes, 647.
Keyt—Sphygmography and cardiography, physiological and clinical, 501.
Kidney; removal of, 56; and liver surgical, 365; disease, hyoscine in, 436; granular and hæmaturia, 465; disease, hydriodate of hyoscine in, 597; malignant tumor of, 782.
Kidneys; suppurating, 77; stays and movable, 508.
King—A new explanation of renal troubles, 629.
Kirwan—Application of the antiseptic principle in private practice, 423.
Klein, Von—A proposition to translate and publish the medicine and hygiene of the Talmud, 509.
Knee-joint; excision of, 55; loose cartilages in, 80, rotation of, 315; new method of excision, 82; phenomenon in diabetes, 307; phenomenon in locomotor ataxia, 311.
Kœberle on the treatment of uterine cancer, 403.

Labium, right, thrombus of, 186.
Labor; cocaine in, 187; forceps in (Wallace), 188; in private practice, 201; paraplegia, its relation to (Parvin), 232; chloral in, 669.
Laceration of perineum (Goodell), 226; Emmet's new operation for, 360.
Lake fevers (Fairman), 221.
Landis—A compend of obstetrics, 405.
Lanolin, 713; mercurial ointment, 57; salves, formulæ for, 598.
Laparotomy; for pyo-salpingitis, 14; in acute peritonitis, 109; for extra-uterine pregnancy, 695; for visceral injuries, 795.
Large doses of turpentine in croup, 315.
Larynx; in child, scald of, 88; is involved, treatment of diphtheria before, 216; deep tubing a substitute for intubation of, 525; stenosis of, 621; intubation of, 792.
Lauder Brunton and homœopathy, 626.
Law—A country doctor's obstetric record, 449, 481.
Lead; in preserved fruit and vegetables, 150; poisoning, 380; encephalopathy (Musser), 641.
Leaves of cloud-berry a diuretic, 248.
Lee—Tracts on massage, 628.
Left-handed people, 479.
Leg-holder for lithotomy posture (Kelly), 747.
Legal, medico-, notes (Riley), 422.
Legislation for the insane, 715.
Lepers, a colony of, 414.
Leprosy; in Sandwich Islands, 61; in Riga, 62; reported case of, 152; in Norway, 445; decoction of mallow in, 538; in South Africa, 824.
Leukæmia, the blood in, 381.
Lewinin or a-kawa-resin, 279.
Liebig's extract, 318.
Ligaments of uterus, 58; operation of shortening the round (Ashby), 289.
Ligation of the innominate, 626.
Ligature of the funis, 186.
Limbs, artificial, the archæology of, 189.
Linear scars in skin, 730.
License, high, 662.
Lithia salicylate, in rheumatism, 508.
Lithotomy posture, new leg holder for (Kelly), 747; suprapubic, 137; position, new apparatus for maintaining the, 715.
Liver, effect of curare on, 54; suppurative inflammation of, 298; hydatid cyst of, 305; oil, Japanese, 639; cirrhosis of, 623.
Lloyd—The electro-diagnosis of neuritis and anterior poliomyelitis, 37.
Lobar pneumonia, an essential fever, 474.
Local thermometry in small pox, 476; temperature in small pox, 571.
Localization, cerebral, 570.
Locomotor ataxy with unusual symptoms, 273; the knee-phenomenon in, 311; ataxy, herpes associated with, 346.
London apothecaries, terebine and, 605.
Longaker—Laparotomy for pyo-salpingitis, 14; cancer of cervix uteri, 385.
Logan on his own disease, 93.
Longevity of 'Friends,' 607.
Love among the elements, 671.

Milk diet, abuse of, 57; in scarlatina, 186; disadvantages of, 249; for Infants, 785.
Mills—The nursing and care of the nervous and insane, 468.

Miscarriage, puerperal convulsions after (Humston), 541.
Missing link, 788.
Mitchell—Midwifery in country, 123; felons, 155; wear and tear, or hints for the overworked, 277.
Mitral regurgitation, tricuspid and, 365.
Mittendorff—Granular lids and contagious ophthalmia, 439.
Mixture, an explosive, 443; soothing for consumption (Johnson) 510; of oil of wintergreen, 667.
Mobility of heart, 21.
Modifications in treatment of stricture of the nasal duct, 331.
Mogiphonia, 466.
Molluscum fibrosum, 714.
Monkey affected with yellow fever, 600.
Monomania or oligomania, which? 555.
Monoplegia, brachial, complicating enteric fever, 537.
Monstrosity, 62; fœtal, 459.
Morbus cerulus from malformed heart, 38.
Morphia in diabetes, 211.
Morphiomania; cocaine for, 84; pulse in, 731.
Mortality; of alcoholists, 181; in public lying-in hospitals of Germany, 465.
Morton—On abdominal section for traumatism, 260, 267.
Mother and child, catalepsy in, 407.
Motor cortical centres, 505.
Mountain climbing, therapeutic value of, 432.
Mouth-wash, antiseptic, 668.
Movable spleen, 474.
Mucous membrane, tumor growing from the, 536.
Muhlenberg—Causes of uncertainty of bovine virus, 125.
Multiple neuritis after diphtheria, 411.
Mumps and peripheral neuritis, 540.
Muscle, the prostate, 694.
Muscles, effect of curare on, 54.
Muscular atrophy, 42; caused by hydro-myelitis, 275.
Musser—Lead encephalopathy, chronic myocarditis, 641.
Myelitis; accompanying measles, 50; multiple neuritis with, 72; hydro-, muscular atrophy caused by, 275; chronic, 650.
Myocarditis, chronic (Musser), 643.
Myoctonine, 216.
Myo-fibroma of the uterus, 204.
Myoma, hysterectomy for, 13.
Myositis ossificans, 782.

Nails, coca butter for (Phares), 188.
Napelline in facial neuralgia, 471.
Napoleon (III.) of medical editors, 189.
Nares, anterior, plugging the, 217.
Nasal; duct, aluminium probe for dilating, 107; and ocular diseases, connection between, 330; duct, stricture, modifications in treatment of, 331.
Necrosed bone, solution of, in spinal absceses, 794.
Nefe—Painful menstruation, 510.
Neisser's gonococcus in gonorrhœal arthritis, 220.
Nematode worms in beet root, 509.
Nephrectomy; for scrofulous disease, 276; extirpation of the uterus and, 440.
Nephritis; scarlatinal, pathology of, 108; following scarlet fever, uræmic convulsions in, 493.
Nephrolithotomy, 556.
Nerve suture, primary, 280, 341.
Nerves in alcohol paralysis, presentation of, 52.
Nervosa, otalgia, antipyrin in 786.
Nervous; insomnia, boldo glucine in, 218; diseases, glycosuria in, 313; system, ophthalmology and diseases of, 438; system, earthquakes on, 477.
Nettle juice, 666.
Neuralgia; chloride of methyl in, 89; electricity in, 91; terpine in, 141; persistent trifacial, 166, 169; facial, napelline in, 471; aconitine in, 506, 666; ocular ointment for, 627; new method of employing electricity in, 635; treatment of, by chloride of methyl, 725.
Neurasthenia, (Arnold), 235, 257.
Neurectomy in facial spasm, 166, 169.
Neuritis; causing neurosis, 22; electro-diagnosis of, 37; multiple with myelitis, 72; electro diagnosis of, 73; peripheral, 174; multiple, after diphtheria, 411; peripheral and mumps, 540.
Neuroses; of ophthalmic origin, 15; at the menopause, 186; genesis of, irritations arising from visual apparatus in, 522; chronic, actual, cautery in, 817.
New drugs, nomenclature of, 24.
New Jersey, State Board of Health Report, 437.
New York doctors and newspapers, 253; Medical Missionary Society, 734.
Night-sweats of phthisis, phosphate of lime, 509.
Nightmare, sudden death from, 400.
Nigricans, aspergillus, 338.
Nitro-glycerine in suspended animation, 220; indications for use of, 345.
Nitrite of amyl in after pains, 761.
Nocturnal enuresis, rhus aromatica for, 444.
Nomenclature of new drugs, 24; in psychiatry, 555, 718; of skin diseases, 724.
Non-specific fungoid growth of the vulva (Simon), 391.
Novel surgical operation, 731.
Norway, leprosy in, 445.
Nose, adenoid growth in, 505; foreign body in, 540; how to check bleeding from the, 656.

Saline purgatives, action of, 634.
Salivary fistula cured by galvanic cautery, 473.
Salol; an antiseptic, 337; in articular rheumatism, 467; in acute febrile diseases, 467; in sciatica, 762.
Salt, common, in migraine, 694.
Salts of quinine, therapeutic equivalents of, 700.
Salvation, angry at his own, 285.
Salves, lanolin, formulæ for, 598.
Sandal-wood in renal colic, 694.
Sanitary qualities of artificial butter (Ludlow), 231.
Santonin, danger in, 791.
Sarcoma; substituting the sixth cervical vertebra, 456; of the brain, 553; osteo- at base of skull, 556.
Satterthwaite—An introduction to practical bacteriology, 658.
Sawdust for surgical dressings, 598.
Scapula; fracture of neck of, 111; transverse fracture of, 116.
Scalp, complete loss of, 790.
Scarenzio's treatment of syphilis, 141.
Scarlatina; milk diet in, 186; maligna, treatment of, 239.
Scarlatinal nephritis, pathology of, 108.
Scarlet fever, treatment of, 659.
Scars, linear, in skin, 730.
Sciatica, salol in, 762.
Science and acrobats, 286.
Scientific medicine and Christianity, 670.
Scirrhus of the mammæ, 790.
Sclerosis; of columns of Goll, 118; primary lateral, 132; of the spinal cord, 366.
Scopoline, 314.
Scrivener's palsy, 155.
Scrofulous disease, nephrectomy for, 276.
Secret remedies of Berlin, 351.
Seguin—Tropical beri-beri, 65.
Sedative; hypodermic injection, 701; perfumery as, 761; solution, 762.
Selection in breeding, 733.
Sensible suggestion, 670.
Sensibility of tympanum in receiving direction of sound, 306.
Sewer poison, effects of, 407.
Sex of the unborn, prognosticating the, 823.
Sexual starvation, 631; hypochondriasis (Horwitz), 745.
Sherman—Rubber goods, 155.
Shortening the round ligaments, operation of (Ashby), 289.
Shoulder; subcoracoid, dislocation of, 184; and arm presentation, 409; injury to 540.
Sialorrhœa of pregnancy, 627.
Sick-headache, case of, 455.
Simon—Non-specific fungoid growth of the vulva, 391.
Sinkler—Case of epilepsy apparently due to general irritation, and cured by circumcision, 229.
Six-fingered family, 126.
Size of pupil, determination of, 716.
Skin; grafting, prosecuted for, 446; diseases, nomenclature of, 724; linear scars in, 730; anæsthesia of, by new method, 789; grafting in scalping, 790.
Skull; fracture through base of, 146; compound depressed fracture of, 306; osteo-sarcoma at base of, 556.
Small-pox; in New York, 191; in Jamaica, 319; inoculation, 381; local thermometry in 475; in Mexico, 512; local temperature in, 571.
Smith, T. C.—Long retention of placenta in a case of abortion, 348; resuscitation of asphyxiated infants, 520; typhlitis and perityphlitis, 617.
Smith—The principles and practice of operative Surgery, 213.
Smith, W. A.—Effects of quinine, 510.
Snake-bite; case of, 122; vaccination against, 447.
Snap diagnosis, 669.
Sneezing, treatment of, by galvano-cautery, 529.
Socotrine aloe leaves for burns, 762.
Soda, bicarbonate, in tonsillitis, 123.
Sodium salicylate with iron in rheumatic affections (Cohen), 677.
Soft chancre in middle ear, 309.
Solanine, 635.
Soluble compressed hypodermic tablets (Wilson), 517.
Solutions, permanent sublimate, 699.
Solution, a sedative, 762; of necrosed bone in spinal abscesses, 794.
Something more about cocaine, 119.
Souffle, uterine, causes of, 344.
Sound, uterine, danger in use of, 703.
Sounding the frontal sinius, 562.
Spartein sulphate, medical uses of, 345.
Spasmodic snorting with rhinitis, 539.
Spastic ataxia, 366.
Specialism in excelsis, 766.
Spermatorrhœa, 85.
Spermatic fluid, bloody, 797.
Sphincter ani, stretching in apoplexy, 783.
Spleen, pulverized in chlorosis, 250; extirpation of, 410; movable, 474.
Spinal hemorrhage, 185; cord, paralysis due to compression of, 245, 498; sclerosis of, 366; concussion of, 557.
Splints, retroflexed for fractures of forearm, 790; fracture of the internal epicondyle treated with, 532.
Spontaneous cure of hernia (Claybough), 348.
Spurious venereal diseases, 762.
Squibb on medical advertising, 535.
Squint, case of, 107.
Starch, iodized, an anæsthetic, 632.
Starvation, sexual, 631.
Statistical horror, 655.
Stenosis of larynx, 621.
Stomach, syphilis of, 26; cancer, sign of, 120; death from perforating ulcer of, 137; digestion, 243; perforating ulcer of, 301; in drunkenness, aspiration of, 472; in intestinal occlusion, washing out the, 562; to relieve pain of cancer of, 701; washing out, the, 824.
St. Mary's General Hospital, Brooklyn, N. Y., 265.
Stomatitis, a remedy for (Corson), 325.
Stone of the bladder, 474.
Strangulated hernia, radical cure, 122.
Strangulation of penis in head of hammer, 599.
Stretching; sphincter ani, 26; the sphincter ani in apoplexy, 783.
Stricture of rectum, treatment of, 179; of the œsophagus, 211, 366; of urethra, treatment of,

242; of nasal duct, modifications in treatment of, 331; congenital, of urethra in infant, 401; of female urethra, 598.
Strictures, urethral whalebone bougies in treatment of (Brinton), 197, 206.
Strumpel—A text-book of medicine, 148.
Strychnine on liver and muscles, 54.
Students, medical degrees for, 446.
Styes, 667.
Styptics in treatment of diphtheria (Swartz), 228.
Sub-cortical disease, paralysis of left leg from, 467.
Subcoracoid dislocation of shoulder reduced by right-angle traction, 184.
Sublimate, poisoning from vaginal injection of, 442; solution, a permanent, 697.
Submaxillary calculus, 463.
Substitute for cat-gut, 380; for court-plaster, 666; for gum acacia in pharmacy, 760.
Substitution by druggists, 279; question, 347.
Successful treatment of acne, 308.
Sudden death, 604.
Suicide by "Rough on Rats," 187; by dynamite, 317; brain of, 365.
Sulphate of duboisin, toxic effects after, 151, 185; spartein, medical uses of, 345.
Sulphur; 735; fumigations with, 215; in chlorosis, 444; water, artificial, a substitute for Bergeon's treatment of phthisis (H. C. Wood), 673; springs, micro-organism of, 797.
Superficial burns, remedy for, 797.
Superior maxilla, resection of, 346.
Superstition against doctors, 287; medical, in the highlands, 479.
Suppositories, peptone, 380, 700.
Suppuration and fermentation, 109.
Suppurative pleuritis in children, 794.
Suppurative inflammation of liver, 298.
Supra-pubic cystotomy, 757.
Supreme court, medical practice discussed by, 638.
Surgeons, genito-urinary association of, 604.
Surgery; of Burmah, 61; ophthalmic, ethyl bromide in, 177; of the pancreas, 178; of the brain, 274, 660; abominal, general work in, 425; paraffin in, 664; progress in, 681; casualties chargable to antiseptics in, 723.
Surgical dressings, 186; mishaps, 208; kidney and liver, 365; hint, a practical, 443; sawdust in, 598; novel operation, 731; treatment of suppurative pleuritis in children, 794.
Suspended animation, nitro-glycerine in, 220.
Suture, primary nerve, 280, 341.
Swarts—Styptics, the especial use of, in the treatment of diphtheria, 228.
Sweringen—A case of puerperal uterine rupture, 674; on paragraphing, 798.
Sympathetic opthalmia, 331; action of cocaine on, 475.
Symptoms; unusual, locomoter ataxy with, 273; ocular, in acute cerebral disease, 367.
Syncope and fainting, 283.
Syphilogenic influence, duration of, 458.
Syphilis; of stomach, 26; Scarenzio's treatment of, 141; hereditary, of tongue, 123; influence of tea-poisoning on, 243; of the ear, 279; reciprocal influence of, on diabetes, 340; treatment of early stages of, 376; effects of, on pregnancy, 377; during pregnancy, 440; phenate of mercury in, 599; notches of incisor teeth, which resemble those of, 784.
Syphilitic; infection through trousers, 221; virus, reproduction of, 307; sucklings, infection of wet-nurses by, 377; albuminuria, 599; placenta, 601; and medicinal eruptions, 724.
Syphiloma of heart, 152.
Syringe, the prehistoric, 670.

Tachycardia, paroxysmal, 304.
Tait operations, three successful, 204.
Talc dentrifice, 762.
Talley—Quinine bimuriate and urea hypodermatically, 577.
Tannin in tuberculosis, 150.
Tapeworm; expulsion of 91; expelled by turpentine, 92; pumpkin seed in, 379; eggs, experiment with, 734; thyroid, as a remedy in, 822.
Tarnier's basiotribe, 491.
Taylor—Manual of treatment, 501.
Tea-poisoning, influence on syphilis, 243.
Teeth; as influenced by food, 84; false, an expensive set of, 447; incisor, notches which resemble those of syphilis, 784.
Telephone, consultations by, 825.
Temperance, to promote, 29.
Temperature, taking the, 25; local, in small-pox, 571; high, in acute diseases over-estimated? 698.
Tents, uterine, their effectual disinfection, 403.
Terebene, renal irritation from, 55; possible danger attending the use of, 282; and London apothecaries, 605.
Terpine in neuralgia, 141.
Terpinol, 315.
Terrible lesson, 724.
Testimony, medical expert, 765.
Test for butter, 377, 416.
Testicle, cure of hernia with loss of (Claybough), 348.
Tetanic convulsions from muriate of cocaine, 556.
Tetanus; contagion of, 89; contagious? 308; rheumatismal, pilocarpine in, 533; treatment of, 655.
Thallin in typhoid fever, 241; fatal results from, 570.
Therapeutic; agent, war as, 192; value of ergotine, 344; value of mountain climbing, 432; electro outfit, cost of, 666; equivalents of salts of quinine, 700.
Therapeutical notes (Kenner), 647.
Therapeutics; hydrofluoric acid in, 58; salicylate of hydrargyrum in (Chaves), 519; fœtal, 632; of Paris hospital, 603; in gynecology, progress of, 710.
Thermo-cautery, new application of, 697.
Thermometry, local, in small-pox, 476.
Thirst, diabetic, treatment of, 381.
Thomson—Transactions of the Academy of Medicine in Ireland, 309.
Thrombus of right labium, 186.
Thuya occidentalis for warts, 57.
Thymol, as a remedy in tapeworm, 822.
Thyroid and cerebral circulation, relations between, 654.
Tinnitus aurium, 5, 35, 358, 387.
Toboggan slide, hurt on, 319.
Tongue; the black, 312; tuberculosis of, 785.
Tonic; pereirine as, 111; a general, 701.
Tonsillitis; bicarbonate of soda in, 123; value of incision in, 372; bicarbonate of soda in, 444; treatment of, 568; epidemic of exudative in children, 625.
Tooth; incisor, torsion of, 282; pyæmia after ex-

traction of, 283; right upper canine in left orbit. 625.
Toothache drops, 154.
Topical applications, treatment of lupus by, 219.
Topographical diagnosis of focal disease, 532.
Torsion of incisor tooth, 282.
Touching incident, 735.
Toxic effects of sulphate of duboisin, 151, 185.
Tracheotomy; practical hint in, 18; in a child, 88; croup and, 314; and intubation in diphtheria, 394; in diphtheria, 411.
Traction in treatment of club foot, 335.
Trade journals disguised and undisguised, 310.
Training of nurses in Japan, 63.
Transactions; of the Medical Association of 117; of Medical Association of Missouri, 117; of Medico-Chirurgical Faculty of Maryland, 117; of the State Medical Society of Wisconsin, 117.
Transmission of anthrax from mother to fœtus, 94; of cholera, 472; of epidemic parotitis, 731.
Transplantation, 91; cornea, 219.
Traumatism, abdominal section for (Morton), 260, 267.
Treatment, year-book of, for 1886, 341.
Trephining for supposed abscess of brain, 412.
Trichinosis of sheep, 123.
Tricuspid and mitral regurgitation, 365.
Tropical; beri-beri, 65; chronic diarrhœa, treatment of, 217; diarrhœa, chronic, pepsin in, 595.
Trypsine and pepsine in urine, existence of, 441.
Tubercle; bacillus, single, how can the presence of be demonstrated, 534; bacilli in sputa, diagnostic value of (Fussell), 614.
Tubercular; meningitis, iodoform ointment in, 24; pyo-salpinx, 205; patients, intercurrent disease in, 281; meningitis (Fussell), 707; meningitis, curability of, 725.
Tuberculosis; natural history of, 20; death by acute, 133; tannin in, 150; treatment of, 316; climatic treatment of, 378; inoculation of, by circumcision, 404; of pharynx, 412; inoculations of in Alaska, 657; action of iodoform on the bacillus of, 696; of tongue, 785.
Tubing, deep of larynx, a substitute for intubation, 525.
Tumor, fibroid, of broad ligament, 9; intra-ocular, 330; cerebral, 719; malignant, of kidney, 782.
Tumors, abdominal, urine in, 91; heart and abdominal, 247; of bladder, diagnosis of, 247; pepsin injections in, 500; malignant, treated with arsenic, 503; cancerous, carbonate of lime the means of arresting the growth of, 722; malignant, turpentine in, 786.
Tuning-forks, vibrations, cataract induced by, 533.
Turnbull—Tinnitus aurium, 5; is chloroform more dangerous to animal life than bromide of ethyl? 105; injurious influences causing deafness, 516; a clinical manual of the diseases of the ear, 628.
Turpentine in chronic catarrh, 33; in croup, large doses, 315; in impetigo, 666; for malignant tumors, 786.
Tympanum, on recurring direction of sound sensibility of, 306.
Typhoid fever, relation between drinking water and (Benjamin), 545; thallin in, 241; antifibrin in, 248, 250; germ, effect of freezing on, 254; bacillus of, 254; treatment of, 369, 379, 665; treated by inhalation of cold air, 371; anomalous form of, 507; treatment with quinine, 565; microbe of, 571, 601.
Typhlitis and perityphlitis (Smith, T. C.). 617.
Throat, worm-like bodies from, 129; the Crown Prince's, 730.

Ulcer; gastric, 115; of stomach, death from, 137; perforating, of stomach, 301; cause of chronic gastric, 564.
Ulcerative endocarditis, 80.
Ulcers; benzoin resin in, 123; benzoin treatment of, 244, 665; chronic treatment of, 183.
Umbilical cord; hernia into, 117; fœtal hernia (Hackney), 509.
Undue frequency of the pulse, 562.
Unique penis syringe (Boone), 221.
University; in the cabinet, 191; foreign intelligence 222, 479, 542; of Pennsylvania, Medical Department Commencement, 602; of Berlin, the, 608.
Uræmia from apoplexy, diagnosis of, 434.
Uræmic convulsions in nephritis following scarlet fever, 493.
Urea and bimuriate quinine hypodermatically (Talley), 577.
Urethra; displacement of, incontinence of urine due to (Goodell), 225; stricture, treatment of, 242; in infant, congenital stricture of, 401; broken catheter, removal from, 592; female, stricture of, 598; injuries and diseases of (Lydston), 609.
Urethral; caruncle, treatment of, 154; strictures, whalebone bougies in treatment of (Brinton), 197, 206.
Urethrotomy; internal, death following, 725; perineal, cases of external (Walker), 771.
Urine; in abdominal tumors, 91; incontinence of, after labor, 220; existence of pepsine and trypsine in, 441; organism producing decomposition of, 468; aspirator in retention of, 474; in female, incontinence of, 506; human, new acid found in, 558; retention of, in a fœtus, 818.
Urticaria and pruritus, 713.
Use and abuse of passive motion, 275.
Uterine; catarrh, iodoform in chronic, 58; appendages, removal of, 282; cancer, when to operate in, 344; souffle, causes of, 344; hemorrhage, hydrastis in, 346; tents, their effectual disinfection, 403; cancer treated by hysterectomy, 403; intra-, amputation of forearm, 539; dilator, a novel, 656; puerperal rupture (Sweringen), 674; pregnancy, laparotomy for extra-, 695; extra-, pregnancy, 751; sound, danger in use of, 793.
Utero; acute pneumonia in, 379; child crying in, 733.
Uterus; palpation of, 15; sounding pregnant, 56; ligaments of, 58; fibro-cyst of, 69, 76; Myo-fibroma of, 205; extirpation of, and nephrectomy, 440; in virgins, posterior displacement of, 708; rupture of, 788.

Vaccination; scars, 90; in Peru, 254; against snake bites, 447; in Africa, 447; Indians, 639.
Vagina, hard chancre of, 217.
Vaginal; injection of sublimate, poisoning from, 442; douche, hot, in acne of female, 714.
Valerianate of quinine, 600.
Vampire legend, 480.

Van Bibber—Fracture of cervical vertebræ, 7; the differential diagnosis of cancer in the mesentery, 193.
Variola, iodoform in, 252.
Vaseline for hypodermic medication, 443.
Vegetable fibres in intestines, 255.
Vegetans, pemphigus, 220.
Venereal; diseases, iodoform in, 664; spurious diseases, 762.
Vermiform appendage; perforation of, 161; appendage, perforation of (Gaston), 551.
Vermiformis, appendix, diagnosis of, 796.
Vermifuge powder, 701.
Vertebræ; cervical, fracture of, 7; lumbar, deficiency of, 92; gunshot wound of, 411; cervical sarcoma, substituting sixth, 456.
Vesico-vaginal fistula, 77.
Veterinary medicine, the study of, 215; school, aid for, 638.
Vibrations of the tuning-fork, cataract induced by, 533.
Visceral injuries, laparotomy for, 795.
Virgins, posterior displacement of the uterus in, 708.
Virus; elimination of, 93; syphilitic, reprodution of, 307; chancroid, the supposed, 459.
Vomiting; during pregnancy, 53; of pregnancy, cocaine in, 249; in young infants, 284; carbolic acid treatment of, 442.
Vulpian—On primary lateral sclerosis, 132.
Vulva, non-specific fungoid growth of, 391.

Waking numbness, 535.
Walker—Oil of turpentine in chronic catarrhal affections, 33; eighteen cases of external perineal urethrotomy, 771.
Walking maniac, 350.
Wall papers, arsenical, 377.
War, a therapeutic agent, 192.
Warts; thuya occidentalis for, 57; remedy for, 540.
Washing out the stomach in intestinal occlusion, 562.
Water; cold in fevers, 246; give the babies, 752.
Westbrook—Angeiospastic angina pectoris, 265.
West Virginia biennial report of the board of health, 437.
Wet nurses, infection of by syphilitic sucklings, 377.
Whooping-cough in cat, 752.
Wight—The bone screw, 264.
Wilson—A new apparatus for preparing dry gypsum bandages, 328; soluble compressed hypodermic tablets, 517.
Wine, diuretic, 762.
Wintergreen oil, mixture of, 667.
Whalebone bougies in the treatment of urethral strictures (Brinton), 191, 206.
Whisky by the pailful, 95.
Whistling barometer, 350.
Whitlow; death from, 409; an infecting, 538.
Whooping cough, 58; treatment of, 90; cocaine in, 220, 728; carbolic acid inhalations in, 568; pathology and theraphy of, 692.
Women, education of, in Germany, 608; fertility of, 656.
Wood, H.C.—Nervous diseases and their diagnosis, 277; artificial sulphur water as a substitute for Bergeon's treatment of phthisis, 673.
Worm, tape, expulsion of, 91; pumpkin seed in, 379; -like bodies from throat and mouth, 129.
Worms, nematode, in beet root, 509; in hen's eggs, 725.
Wound, gunshot, epilepsy after, 370; penetrating abdominal, 410; gunshot, of vertebræ, 411; of the chest, 681; of the heart, 731.
Wounds, gunshot, of abdomen, 283; value of hemorrhage in treatment of, 724.
Writers' cramp, apparatus for relief of, 721.
Wyeth—A text-book on surgery, general, operative and mechanical, 468.

Year-book of treatment for 1886, 341.
Yellow fever, inoculation a preventitive of, 536; monkey affected with, 600; microbe of, 701; in Key West, 764; measures taken to prevent the spread of, 766.

Pallas Syringe."

[From the *London Medical Record.*]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche."
See page 8.

WHOLE No. 1557.] JANUARY 1, 1887. [VOL. LVI., No. 1.

SOLUBLE
PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1054-15556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant. Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

COCAINE INEBRIETY.*

BY T. D. CROTHERS, M. D.,

Superintendent Walnut Lodge, Hartford, Conn.

My experience in cocaine inebriety is limited to seven cases. Two were under my care for treatment, three came personally for advice, and two consulted me by letter.

In the cases under my care a correct history was obtained; in the five cases who sought advice by person and letter, their own personal statements were the chief sources of information. In two cases their statements were confirmed by other parties, and where such statements corresponded with the facts in other cases, they were accepted as probably true. The following are some of the facts which appeared from the history of these cases:

Alcohol, opium, chloral, bromides, and other narcotics, had been used more or less to excess in all these cases before cocaine was taken. In four of these cases coca had been used for months before cocaine was tried. Hence, they were all literally drug maniacs, or inebriates, whose special symptom of disease is a morbid impulse for narcotic drugs, which will bring rest and relief to the organism. Some details of the history of these cases will indicate the leading facts.

Case 1. Had been under my care twice before for alcoholism and opium excesses, at intervals of two or three years; he had taken cocaine for six months, but latterly had suffered a delirious mania after using this drug, and becoming alarmed, came to me for treatment. He was a "repeater," who alternately went from one drug to another for relief.

Case 2. Under my care; had been treated for morphine excess two years before. He had used cocaine for one year, and had been a moderate and occasionally excessive user of spirits. He belonged to that class of drug-takers who try everything that promises relief for real or imaginary ills.

Case 3. Not under my care; was a landlord who had used alcohol for a long time; finally he resorted to chloral and bromides to break up the alcoholic impulse. He suffered from rheumatism, and took coca and then cocaine. He had used the latter for six months, and was alarmed at the extreme debility and nausea it produced.

Case 4. Not under my care; had used the bromides for insomnia, then changed to alcohol, and finally used cocaine; he had taken cocaine eight months, and was greatly debilitated, had night-sweats, and thought he had consumption.

Case 5. Had used alcohol for years, then tried chloroform, finally used coca, then cocaine; the latter he had used for over a year; he was anæmic, and had deranged nutrition, and his mind was greatly enfeebled.

Case 6. Facts by letter. Had used patent bitters for years, then wine, and finally coca and cocaine. He was delirious from the latter at times, and unable to do business.

Case 7. Facts by letter. Had always used wine and cider; took bromides for sleep, then tinct. coca, then cocaine.

In these cases the use of cocaine was merely another stage of the drug mania. The use of alcohol and other narcotics to ex-

*Read at the annual meeting of the American Association for Cure of Inebriates in Brooklyn, November 15, 1886.

cess had developed a state of the nervous system which called for relief, and they turned to any drug that would answer this purpose. Such persons often develop a credulity and a morbid impulse to try everything that promises relief, hence they are pioneers among experimenters.

Another fact of general interest from these cases was an inherited neurotic taint or tendency. Thus, four cases inherited a marked nerve defect from their ancestors; two had acquired a brain and nerve debility, and no history on this point was obtained from one case.

To particularize, Case 1 had an inebriate father and consumptive mother, and was an unstable, impulsive man.

Case 2 had an insane father and an epileptic brother, and two inebriate uncles on his mother's side.

Case 3. Had a pauper ancestry, paralysis, hysteria, and great eccentricity of conduct in parents and near relatives. He was a very nervous, excitable man.

Case 4. Had two uncles in insane asylums, mother died of consumption, one brother an imbecile, and his father was a wine-drinker.

Case 5. Had a severe army experience, was a neurotic dating from wounds in the army, attacks of malaria and typhoid fever.

Case 6. Had a head injury in childhood, a sunstroke later, followed by a most persistent dyspepsia for years.

I think that further study and experience will sustain these two facts:

First. That nearly all the cocaine, bromide, chloral, ether, chloroform, and coca inebriates, are complex cases or those who have used other drugs, including alcohol and opium, and have finally turned to some one of these drugs. That all of these cases have had a period of drug preparation, and may be called drug neurotics, who are always using some similar compound. Probably a large proportion of the alcohol and opium cases begin without this drug taking, but it may be said that the cocaine, bromide, ether, chloroform and chloral takers follow as a rule from states of previous excess in drug taking.

The second fact is that nearly all these drug maniacs are neurotics from inheritance and acquired states of degeneration. The morbid impulse for this or that drug is only another symptom of brain defect.

It is evident that a study of the symptoms and effects of any new narcotic must include the heredity and history of other drug excess.

Where these clinical facts are not considered, such cases will present many confusing histories.

While cocaine has come into prominence as a local anæsthetic, the statements of its action in large and long-continued doses are of necessity vague and contradictory. Exhaustive histories and studies of many cases are needed before accurate conclusions can be reached.

The following are some of the facts which seem to be peculiar to cocaine cases. The first effect seems to have been that of a transient stimulant; a most agreeable exhilaration ending in sleep, with no unpleasant after effects. Later, when large doses were taken, the general stimulation at first became a marked exaltation, and in many cases a mania. The mind seemed to be in a whirl from one thought and subject to another, without ability to concentrate on any one object.

This stage would of course vary largely with the case and conditions, and resembles alcoholic delirium, only it is more diffuse and transient. The second stage, that of sleep and stupor, comes on quickly, and the desire for sleep seems overpowering and intense. The stupor is more like that from opium, only less pronounced and more easily broken up. On awakening, the least exertion is followed by extreme and most wretched debility; nausea and vomiting came on in some cases, also a pronounced melancholy which seeks relief from this drug again. The three stages of stimulation, narcotism, and depression, seem very intense, and may be called literally mania, coma, and melancholy.

In three of the cases I have noted, the first stage of exhilaration was protracted for a long time by taking small doses. The state produced was one of great satisfaction, with freedom from care and contentment with everything. After a time, the sleep impulse became annoying for the reason that it was not gratified. A short sleep would be followed by a waking period, filled with similar ungratified impulses. Large doses had to be taken to break up this impulse. In two cases large doses were taken for its rapid narcotic action. The first stage was to the patient a short confused exaltation, with a pleasing rush of thought and events. To others, this stage was a wild confused mania. The sleep which followed was deep and profound. Profuse perspiration and general failure of nutrition followed.

In one case under my care a relapse took place and I observed the heart's action. In the first stage of mania it was increased to

108, and as stupor came on, ran down to 70, but at all times was regular. The temperature did not vary over one degree, and was generally higher than natural. The pupils were at first dilated, then contracted. A profound anæsthesia of the mucous membrane of both eyes, nose, and mouth was noticed. The narcotism resembled that from opium. On awakening a general prostration was apparent; the pulse and temperature were lowered. The stomach would not retain anything. Intense hyperæsthesia pervaded all parts of the body; insomnia and the deepest melancholy was present, and yielded slowly to treatment.

Another case, of an intelligent man, who described the first effects of cocaine as a sudden expulsion of all aches and pains, followed by a quiet satisfaction and a most pleasing natural sleep. Later, when taking large doses, his wretchedness would lift like a cloud, and great activity of both mind and body that was pleasurable followed. After the narcotic stage ended, he seemed to be worn out, without any hope or faith in the present or future. Every sensation was most miserable. Taste, sight, hearing, and feeling were all perverted, and, as he expressed it, seemed in league to drive him to madness.

In one case the mania of the first stage was noted by loss of memory and inability to recall any event of the past. The duration of the different stages varies greatly. Sometimes the mania of the first stage is longer than the period of narcotism, and vice versa. In some cases the last stage of melancholia is of great length.

So far, I believe the common sequelæ of alcohol and opium inebriety, particularly the neuralgias and congestions, are much less frequent in these cases. But in their place appears a general mental and muscular degeneration with extreme depression, particularly of the nervous respiratory, circulatory, and vaso-motor systems. I think it very probable that the continued use of coca is often followed by excess in cocaine. One of the reasons is that the various preparations of coca on the market are compounded often from dangerous alcohols. In this case the action of coca is destroyed and replaced by the degeneration which comes from the alcohol. Thus, when tinctures of coca are given, made from wood spirits, the effect of this remedy is to produce degeneration of both brain and nerves, which will seek relief from narcotics of any kind. I am also persuaded to believe that cocaine inebriety, or coca mania, will never become prominent, and will be confined to a class of neurotics who, by the use of other drugs, have prepared the soil for this new drug-mania. It will never take the place of alcohol or opium in common use. Its action is too uncertain and transient. The present novelty and glamour about its effects will die away when its real value is ascertained. The element of contagion in these cases presents a curious psychological phase; thus some extravagant newspaper statement of the terrible effects of this drug will rouse curiosity to test it. Or the printed history of a case appearing as daily news draws the attention of neurotics, and it is safe to say that a large per cent. not only purchase, but test this drug on themselves. Cocaine should not be used as a substitute in breaking away from the use of other narcotics. It should not be used in large or long-continued doses. In melancholia it is likely to provoke the disorder it is supposed to break up. It cannot be used indiscriminately. However valuable it may be, there is a certain limit to its power and practical use.

The treatment of cocaine inebriety is the same as that of alcohol or opium cases. Forced abstinence from the drug, rest, and building up the system, are the general methods pursued. More profound degeneration and debility exist than in other forms of inebriety requiring a longer time for successful treatment.

States of mania and melancholy often continue for some time after the use of the drug is given up, and disappear very slowly. It is for these states that special surroundings and care are essential. The prognosis is always uncertain. The craving for drugs for their effects may be broken up and restoration follow, but such cases generally are unable to bear much exposure, and not unfrequently relapse on the slightest temptation. In the cases under my care, both recovered, but will probably relapse, using the same or some other drug in future.

The following conclusions are sustained by the best evidence which has been presented so far.

The use of cocaine to excess in persons who have never used alcohol or other narcotic drugs before, is very rare.

Among inebriates and drug maniacs, cocaine inebriety is no doubt increasing.

Its peculiar dangerous effects on the body will prevent its general use as an intoxicant to any great extent.

It acts more rapidly than opium, but its effects pass off more quickly.

Its first effect is more exhilarant than alcohol, but it is uncertain and variable.

This stimulant action develops mania, followed by narcotism and melancholia.

When given in cases of melancholia in large doses, it changes the case to mania, then finally relapses bring back the case to melancholia again.

As an intoxicant, it is more dangerous than alcohol or opium.

As a form of inebriety it is more difficult to treat, requiring a longer time to break up, because of the physical and psychical complications.

It cannot be used as a substitute for any other narcotic, or as an antidote or remedy.

THREE CASES OF CARCINOMA OF THE BREAST.

BY E. CHENERY, M. D.,

Of Boston.

The following cases of cancer of the breast are of some interest by way of practical suggestions:

Case 1. This was in a widow lady of sixty and mother of several children. She was a stout, active woman. One or two sisters had died of the disease. The disease in her case had been quietly progressing when she called to her aid a professional "cancer cure" doctor, who had the care of her case for a long time. Nothing he did amounted, apparently, to anything. I am surprised at the firm hold these men get on their patients, and how long they are permitted to try their efforts when even the common observer sees they are valueless. It almost seems that to be "loud-mouthed" is, in some places, quite as profitable as to dollars and cents as to be "loud" in intelligence and skill. But the fellow had at this time fallen upon a real cancer, and not something out of which he could extract professional capital. Notwithstanding this fellow's large pretensions, the patient grew gradually worse, and at length he was discharged. At my first visit I found the disease, which had begun in the left breast, and spread to the right and to all the skin between and above them. The skin was red, thick, and hard like a coat of mail. Over the left gland there were several ulcers, but one beneath and to the left of the nipple was by far the largest, and had well undermined that appendage. It was plain that little could be done but to smooth her course downward, hoping that the end might soon come. Various deodorants and antiseptics were resorted to; but that which seemed the most useful was diluted hydrochloric acid. It made the part feel better, and was very effectual in lessening the odor. She had good flesh, and was not emaciated, and there was but slight showing of the peculiar cancerous cachexy. We expected her to live some time, when septicæmia set in, and, inside of a week, carried her off, thereby showing itself to be the most beneficent case of septicæmia I ever saw. I had never blessed the Lord for septic infection before, and haven't much since. Though dreaded as this poisoning is, we may yet come to see it as an angel of mercy, working higher ends than we ever supposed it capable of. Here it was certainly a blessing.

Since that time I have seen another similar case, in consultation, where the disease had eaten away well-nigh the whole front of the chest, and spread down upon the abdomen, yet septicæmia never came to her relief. Why not?

Case 2. Woman, 45, married, mother of two children, in easy circumstances. Father died of epithelioma of the lower lip. Her disease, like the other, was in the left breast. The skin was not involved. A degree of condensation had, however, taken place in the connective tissue between the breast and the muscles. I advised its immediate removal. The patient, however, waited a little to make up her mind, when she saw the newspaper advertisement of Chian turpentine, then just getting popular, and took that. At her request, I obtained it for her from a reliable party. At first it relieved some of her symptoms so that she thought it was doing her good. The disease deceived her by going deeper instead of outward to the skin, so she was not aware of its progress till it reached the pleura and produced a fatal pleuritis. I have always regretted that the operation was not performed. The operation first, and the turpentine afterwards, would have been the rational order. As it was, the turpentine, like the German doctor, "cured her till she died," and probably never stayed the disease at all.

Case 3 occurred in a widow of 63, and was in the right breast. It did not involve the skin, but had reached the pectoral muscle. I advised its removal by the knife, to which she consented. Of course it was necessary to sacrifice considerable of the muscle. I used carbolized catgut for ligatures and sutures, and mopped out the wound with 95 per cent. alcohol, then with solution of boro-glyceride, then with alcohol again. Comp. tincture benzoin was painted over the incision, and absorbent cotton stuck on to it and bound. All the instruments, sponges, etc., were made clean by carbolic acid, and

the water used had been thoroughly boiled. So far from being a painful operation, the patient, coming out of the ether and finding herself in bed, inquired if the doctors had given it and gone. No pain or tenderness over the wound was experienced afterwards, and every part healed by first intention. Between two and three years of immunity from the cancer passed, when she suddenly succumbed to a stroke of apoplexy.

Now, not inferring from this case alone, but from a wider range, I ask, What sense is there in letting this loathsome disease have its own way to work its own end? It may and probably will in time recur. If it does, and ultimately defies all our efforts, will not a timely removal of cancer, when and where it can be done, materially diminish the sum total of suffering? In some cases it will not return. Many years ago I removed one from the upper lip of an aged lady, from which she has remained free to this time.

Of course the soft cancer is attended by rapid cell development and diffusion, and gives no show for its entire extirpation. The nature of certain localities and the too long neglect of the operation in cases which at first might have been removed, bars this procedure, and dooms the patient. When, however, the disease is local, and can be entirely extirpated, it ought to be done. And if, as is taught, the disease is a local disease to begin with, it ought not return if the whole of the infected locality can be taken away. But I fear the operation does not frequently realize as much as it promises, because it is not properly done. A thistle in the garden may be taken up by the roots, and removed, but if by a careless shaking of its ripe heads the seeds are scattered on the ground, there will be a return of thistles in that garden. So I suspect many an operation for the removal of cancer is a failure, not because the whole disease was not removed, but because the cells of the cancer were sown in the wound by cutting or pricking the morbid mass. Then what have we gained? Let us think.

SOME RECENT STUDIES AND OBSERVATIONS ON TINNITUS AURIUM.

BY LAURENCE TURNBULL, M. D., PH. G.,

Aural Surgeon Jefferson to Medical College Hospital, Phila.

For many years our knowledge of this subject was very obscure, and all noises in the head or ears were classed as *nervous*. No one, that we are aware of, has given the subject as much study and careful observation. As early as 1874, we published our first essay on the subject, and the third in 1885*—views we then expressed have been confirmed. To these, our most recent studies, there have been added with many new facts as to the causes producing these noises, and their prevention and treatment.

We are now, almost in every instance, able to determine the cause of any form of noise in the head, and ears, and by the aid of various instruments of precision, refer them first to the part of the head or ear that they properly belong.

Again, we can reduce the noises to three classes, and almost as soon as the patient gives us a history of the form which he suffers, at once class it as belonging to—

1st. The constant rushing and knocking or pulsating noises. This is the most rare form, and depending almost always upon hyperemia, venous or arterial effusion of blood, serum or pus in the labyrinth, semicircular canal, ecchymosis in the vestibule or hyperemia of the cochlea; extra aural causes, as aneurism, anæmia, chlorosis, lithæmia, temporary or permanent organic changes in blood-vessels in and around the ear.

The second class (2) are what we term moist sounds, and are of great variety, depending upon the patient's occupation and intelligence, but are chiefly described as "gurgling, bubbling, boiling, singing, whistling, shell-like roaring, etc." These forms of moist sounds indicate the presence of fluid on the tympanic membrane or in the cavity, catarrh of the eustachian tube, irritation of external auditory canal or mastoid cells or post-nasal spaces and pharynx.

Third (3), dry roaring and ringing noises, comprising a large number of diseases of the auditory nerve of a direct and reflex origin. First the direct, as chronic non-suppurative middle ear catarrh, diseases of the muscular apparatus of the ear and nervous supply, cerebro-spinal meningitis, pressure of tumors in and about the ear and auditory nerve, Meniere's class of symptoms, and syphilitic disease of the nervous apparatus of the ear.

HABITS OF THE BODY THAT INDUCE THE NOISES.

There are certain individual habits which congest the parts either temporarily or permanently, which produce tinnitus; as the free use of stimulants and tobacco, a full meal,

* Imperfect Hearing, and the Hygiene of the Apparatus of Hearing, with the Prevention of Deafness, by Laurence Turnbull, M. D., Ph. G. Third edition: large 8vo.; cloth. J. B. Lippincott & Co., 1885.

great bodily or mental fatigue, unusual effort—as public speaking, too much sleep after a full meal, study, or reading with a gas-burner or oil lamp near the head, etc.

There are also certain vocations that increase the intensity of the noises, as in telegraph operatives, locomotive engineers, boiler-makers, machine-workers in cotton, or wool factories.

MENTAL INFLUENCES.

There are certain influences, both internal and external, which produce increase or diminution of these sounds. A happy frame of mind and pleasant dry weather will diminish these sounds. Worry or ill temper, meeting strangers, or wet damp cold weather, or its opposite, intensely hot, as also a close room, will increase these sounds. Pleasant occupation or active work, riding in a carriage or railroad, the patient will not notice the sounds. These sounds are not so intense during the day-time, but they become much louder because everything is quiet as at night. This is especially the case if the individual suffers from dyspepsia or indigestion. The subjective noises are produced or increased in woman by sickness of the stomach, or during pregnancy and the puerperal state, and before, during, and after menstruation.

There are various forms of reflected symptoms of tinnitus when there is internal disease. Painful noises are produced in the ear from diseased conditions of the kidneys, more especially diabetes, also in Bright's disease, which latter often causes effusion of blood and serum in the middle ear, so also a peculiar form of tinnitus which I have fully described in the *Journal of Am. Med. Assoc.*, 1885.

There is a change in the subjective noises in diseases of the middle ear, when pressure is made, with the finger, upon the mastoid process or on the first cervical vertebra. Noises which are often weak and feeble are apparently increased in intensity by closing the external meatus by the finger.

(*To be continued.*)

BINIODIDE OF MERCURY AS A GERMICIDE.

BY B. F. ACKLEY, M. D.,

Of Du Bois, Pa.

Having noticed in your excellent journal of November 27 an extract from the *British Medical Journal*, referring to a former article by Dr. C. R. Illingworth, on the efficacy of the biniodide of mercury as a specific in scarlatina and diphtheria, I feel it a duty to give you my experience in the use of that particular preparation. Having tested its germicide qualities in a number of cases within the past five years, I am convinced that it is the specific and germicide "par excellence," at least in diphtheria, and possibly in allied affections.

My conversion to the use of it as a germicide dates back to my reading an article on mercury and the efficiency of its different preparations to destroy parasitic life (see vol. i. "Trousseau's Therapeutics," Woods' Library for 1880).

I had known of its use in an empirical way, and used it myself, but having not yet accepted the germ theory, and loth to part with my old friend and "vade mecum" for twenty-five years, Greenhow on Diphtheria, my treatment was mixed and less successful. Convinced that I had found the poison for the "bug," I have since used the biniodide to the exclusion of all other remedies, and administer it in the form of powder combined with "saccharated pepsin," placed dry on the tongue, and do not allow liquids in any form until ten minutes later, becoming mixed with the saliva and diffused over the mouth and fauces; the local germicidal effect is thus prolonged, and it has the same systemic effect as if swallowed at once. I do not use or consider necessary local treatment by pencil or insufflation to the fauces, or externally to the throat by liniment, except as a "placebo." I believe many children have been lost through officious and forcible attempts to apply irritant local remedies to the fauces, resulting in the child's positive refusal to take even necessary nourishment and stimulants. I give small doses every one or two hours—age, frequency of repetition, and urgency of symptoms considered. I disallow solid food, and disregarding fever, usually give wine whey, from the first substituting brandy and egg punch if exhaustion becomes marked. Convalescence sets in usually within four or five days from the commencement of treatment, as I have noticed in six typical cases, all children of miners who had moved to this locality from Tioga county, Pa., where a severe epidemic was prevailing at the time, a child having died out of one of the families before their departure.

One of these cases, the last one treated, a young man twenty years of age, in whom the symptoms were well marked, will serve to show progress.

When called, I found the tonsils and contiguous parts much congested and of a dark-red color, the posterior wall of the pharynx

having a glazed appearance, the left tonsil half covered with dark-colored patches, and concomitant symptoms all fully developed.

℞. Hyd. biniodid., gr. 1-16.
Pepsin sacch., gr. 6.

Every two hours, to be taken dry on tongue and slowly swallowed. Wine whey between doses. As a liniment I use

℞. Kerosene,
Ol. olivæ. Equal parts externally to throat.

On second visit, twelve hours after, I found the patches coalesced on left side and covering two-thirds of the tonsil, and appearing on the right side, but of a lighter shade. Swelling and redness unchanged; bowels had moved twice. Continued treatment.

Third visit, twenty-four hours after, I found an improvement in all symptoms, the deposit thinning and lighter in color as if melting away; bowels had moved three times since last visit, attributed to the pepsin. Continued powders every four hours.

Twenty-four hours after, a thin film only remained on left side, with slight swelling and tenderness of sub-maxillary glands on left side. Continued powders every six hours. In two days after, he reported well. As a solvent, in this case only did I combine the biniodide with pepsin (Houghton's); the other cases were children under twelve years, and were all treated with it in fine powder, with sugar of milk.

INTRA-OCULAR CANCER IN A CHILD.*

BY J. J. CHISOLM, M. D.,
Of Baltimore, Md.

Dr. J. J. Chisolm had occasion to operate to-day on a case that was calculated to appeal to one's sympathies. The patient, a little girl of about two years of age, was brought to him by her mother in order that he might rectify, if possible, a peculiar expression that she had noticed in one of her child's eyes.

At a glance he noticed the yellowish appearance that is so characteristic of intra-ocular cancer. The mother stoutly refused to permit ophthalmoscopic examination until she was made aware of the serious nature of the trouble.

Upon examination, he found nearly the whole of the eye filled with a gliomatous tumor formation, not, however, invading the optic nerve, but apparently confined to the retina and sub-retinal coats.

After consideration, the mother consented to permit enucleation to be performed.

In the opinion of Dr. Chisolm there will, in the view of the fact that the growth does not involve the optic nerve nor any of the socket tissues, not having broken through the outer coats of the ball, be no return; but should it have infiltrated the nerve or socket tissues, the prognosis would have indeed been very grave.

The common history of these cases is that when they are present there is a characteristic yellowish reflex that shows plainly through the pupil even without ophthalmoscopic aid. The growth continues to develop, the optic nerve becomes infiltrated, likewise the outer coats of the ball, until perforation and extension to socket tissues occurs. They are accompanied by great pain, increasing as the trouble progresses, and they not infrequently prove fatal in about one year, unless aid is given sufficiently early. Recurrence is the rule after operation if the nerve or socket tissues are involved. In this case the doctor does not anticipate any return of the growth, as it was an unusually favorable case for operation. He has also seen a child in which both eyes were affected by a similar pathological process. No operation was done, and when the child died its eyes were nearly the size of its head.

* Abstract of a paper read before the Baltimore Academy of Medicine, November 16, 1886.

FRACTURE OF CERVICAL VERTEBRÆ.*

BY W. CHEW VAN BIBBER, M. D.,
Of Baltimore, Md.

Dr. W. Chew Van Bibber said he had recently been invited by Dr. Robert Johnson to attend a post-mortem examination upon one of his patients who had died under rather peculiar circumstances.

The subject was a well-built man, a carpenter by occupation, who while pursuing his calling had a fall from which he recovered only partially when he attempted to return to his work, but found it impossible to continue. He came to Baltimore for treatment, and was under the care of Dr. Robert Johnson for four or five weeks previous to his death. There was a swelling on the back of his neck about the fourth cervical vertebra, and besides this no other lesion could be found. He made no improvement under treatment, and finally died.

At the autopsy, made by Dr. Wm. T.

* Abstract of paper read before the Baltimore Academy of Medicine, November 16.

Councilman, nothing was found to account for death until section of this swelling in the cervical region was made. Here there was found a complete solution of continuity of the bony column, the true nature of which was not then made out, as a histological examination of the tissues was necessary.

Dr. Van Bibber referred to several cases of fracture of cervical vertebræ that have occurred in his practice, but none of them behaved as this case did. They were all seriously affected from the first.

He referred to the case of Sir Charles Bell, in which the patient who had received an injury in the cervical region, in bowing himself from the surgeon's presence, completed the partly severed bony segments and dropped dead upon the floor.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

Service of Dr. J. M. Da Costa.

Diabetes Mellitus—Rapid Course.

The patient was a man of forty years, admitted to the hospital November 23, 1886. Family history throws no light upon the case. Mother still living; father died of phthisis.

When a child, the patient had a fall, striking his head, but followed by no immediate result; however, the next morning at breakfast he fainted, and ever since that time he has been subject to severe headaches. He had no sickness until four years ago, when after exposure, he had a *chancre*.

The present illness began only nine weeks ago with great thirst, vertigo, loss of flesh and strength, and he passed a large quantity of urine, having to rise several times during the night. All these symptoms had been growing rapidly worse, till a few days since he was seized with a slight cough.

On admission, he was greatly emaciated and weak. Temperature 99°, pulse 92, respiration 28; tongue rather dry and coated. At the central portion of the right lung there was some consolidation. The urine, which was 1042 specific gravity, contained sugar in great quantity, was acid in reaction, and showed no albumen. He was ordered five-grain doses of potassium iodide four times daily.

November 24. His temperature was 102⅘°, pulse 100, respiration 28, and he complained of great weakness.

November 25. His temperature rose to 105°; was much weaker. Heart sounds seemed weak, but no murmur could be distinguished.

November 26. He complained of severe abdominal pains, seemed still weaker, otherwise his condition not much changed. Urine at this date contained a trace of albumen; *no casts*; a large amount of glucose, and specific gravity down to 1030.

November 27. He was delirious through the night, and passed only two pints of urine. The urine gave off a strong odor of acetone. He seemed gradually passing into a comatose condition, and died on the 28th.

Autopsy four hours after death finds body much emaciated, and rigor mortis well marked. On removing the skull cap a large amount of serous fluid escaped from beneath the dura mater.

Upon the convexity of the cerebrum there is considerable opacity of the pia mater, and some of the convolutions are shrunken.

In the anterior part of the longitudinal fissure there are quite firm old adhesions between the two hemispheres. The lateral ventricles contain a small amount of serous effusion.

Substance of the cerebrum is very firm in most parts. On section of the basal ganglia they are found to be softened in some of their layers. The cerebellum is softened throughout, except the corpus dentatum and the central white surface.

Upon section of the right crus cerebri, a dark-colored elliptical spot is found, which looks like an old spot of hemorrhage, or the remains of a gummatous growth. Below this point the right crus is softened.

The pons is softened throughout, but especially upon the right side, which is shrunken. The substance of the medulla (involving the tissues which form the floor of the fourth ventricle) is softened as far down as the beginning of the cord. The softening is here also most marked on the right side, but the difference in the two sides is less marked than in the pons.

Heart weighs eight ounces. The left ventricle is slightly hypertrophied, compared with the right, and contains a very firm fibrinous clot.

Valves are normal, except slight atheroma of all those on the left side.

Aorta.—Marked atheroma, with slight dilatation.

Lungs.—The upper part of the left lung is pretty well solidified, and many nodules can be felt in other parts, as well as numerous fine shot-like bodies. Right lung presents similar conditions. The extreme apex

of left lung contains a cavity with thick walls, and at numerous other parts of the lungs are areas of softening, filled with fluid, which was examined for tubercle bacilli, but with negative results.

Liver is small, weighs two pounds and ten ounces. Upon section of this organ a strong odor of acetone is emitted (or an odor like the smell of the breath in acetonæmia).

Gall-bladder is much shrunken and contains a little pale-yellow bile.

Kidneys.—Not markedly enlarged; moderately firm; slightly swollen. Cortical substance is pale, striated, and opaque. Capsule is easily removed, leaving a smooth surface. In the right kidney there is one small nodule, which looks like a miliary tubercle.

Spleen is very small, and weighs two ounces.

Pancreas is very small.

Tissue is very pale. It appears shrunken and atrophied.

This case was possessed of considerable medical interest. The diagnosis, *i. e.*, diabetes, was easily made. Diabetes suddenly developed, and running a rapid course to a fatal termination is by no means common. Can we explain the cause? The disease was hardly produced by the fall some thirty or thirty-five years previous. Patients with acute diabetes are subject particularly to tubercle in lung. This may be latent or acute. They commonly develop either acute phthisis or catarrhal pneumonia.

The cause for the development of diabetes in this case is remote, but I believe it to be of cerebral origin; probably induced by syphilis.

Salicylate of sodium in the treatment of diabetes gives better results than any other remedy; far better than opium, and has not its disadvantages. Indicated in gouty and diabetic patients in sufficient quantities, it decreases the diabetes and keeps off the gout. Salicylic acid and the other sodium salts have been tried, but do not give as good results.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, December 2, 1886, E. E. Montgomery, M. D., vice-president, in the chair.

Fibroid Tumor of the Broad Ligament.

Dr. W. Constantine Goodell exhibited for Dr. W. Goodell the right broad ligament containing an enlarged ovary, and close by its side, but distinct from it, a fibroid tumor of the shape and size of the non-gravid womb. The left ovary was also greatly enlarged. It contained a cyst, which burst into the cavity of the abdomen while the woman was being examined four days before the operation, which took place in Dr. W. Goodell's private hospital on June 22d, and she recovered promptly. Her symptoms were painful, and feeble locomotion, constant ovarian pains, menorrhagia, followed by prolonged dribblings of blood, and a retroversion which could not be rectified on account of the tender and dislocated ovaries. She had been under treatment for several years, and without benefit; but since the operation she had greatly improved.

He also exhibited for Dr. W. Goodell an

Intra-Ligamentous Ovarian Cyst,

With the following history: The girl, aged eighteen, had been growing large for two years, and her health also began to fail, but a tumor was not suspected until six months ago, when she was examined by Dr. George H. Woods, of Pine Grove Mills, Pa. Discovering a cyst, he sent her to Dr. W. Goodell. The operation was performed on September 25th, at his private hospital, and was a difficult one, because most of the cyst lay between the folds of the right broad ligament, and the rest of it was adherent at every point to intestines and abdominal wall. It was enucleated so completely that no pedicle was left to tie. He exhibited it mainly to show the greatly hypertrophied and dilated oviduct, the walls of which are very thick, and were filled with pus. The left ovary being of the size of a goose's egg, was also removed. It contained pus, and also was enveloped in the broad ligament, and had to be shelled out. In spite of the complications, this case recovered promptly. Dr. W. Goodell had had during the past year another case of intra-ligamentous cyst of the most formidable character. The cyst was attached to nearly the whole of the colon, to the small intestines, to the bladder, and to the whole surface of the womb, measuring five inches in length. The lower portion lay between two layers of the broad ligament, from which it was shelled out without a pedicle. The parts were so disorganized that the second ovary could not be found, nor was it possible to determine positively which ovary was removed. But the presumption is that it was the right, because nearly the whole of the right ureter, fully ten inches of it, had to be carefully dissected off from the cyst wall, and from between the

layers of the broad ligament. Many ligatures were used, and very little blood was lost, but the patient died on the table from shock, while the wound was being closed. Before this death, Dr. W. Goodell had had twenty-two successive ovariotomies, all of which recovered, and he had had eight successful cases since, making in all thirty cases, with but a single death.

Dr. John M. Taylor, upon invitation from the chair, remarked that the first case reported by Dr. Goodell had been originally under his care. He had attended her in labor, and nothing abnormal occurred in the puerperal period. He had examined her six weeks later, as is his custom, and found nothing wrong. Some months afterwards she had a miscarriage; there was some placental retention, and it was followed by ovarian tenderness and signs of inflammation, which gradually increased; the ovaries became enlarged. Nine months after the miscarriage, the operation was performed. An interesting question is, When did the tumor begin?

Dr. Montgomery remarked that there was a resemblance between the tumor and one horn of a uterus bicornus. Was there a distinct separation between the uterus and the tumor, or could it have been such a horn?

Dr. W. C. Goodell stated that the tumor was separated from the uterus by an inch. The tumor has greatly diminished in size since it was placed in alcohol.

Dr. Howard A. Kelly exhibited a

Parovarian Cyst

weighing thirty-seven pounds. The patient, a young woman, nulliparous, had noticed the tumor one year before. The character of the percussion wave and the evenness of the belly wall decided a correct diagnosis. A point of interest was the flatness of the anterior abdominal wall, with more fullness in the flanks than the speaker had ever before observed in a cystic tumor. The tumor was removed through a two and a half inch incision. The fluid was viscid and yellowish. There were no adhesions. The broad pedicle was transfixed and tied, and over this a tie made embracing the whole. The wound was closed by silkworm-gut sutures—five to the inch—and the whole operation completed in thirty-six minutes.

It is two weeks, to-day, since the operation. The patient is sitting up in a rocking-chair. She had no fever at all, a pulse daily growing slower, and felt well. The cyst was one large cavity, containing several cauliflower vegetations on its inner wall. The ovary lay intact on its outer wall, and the tube, about ten inches in length, was drawn out over it.

Removal of Ovaries and Tubes for Subinvolution and Chronic Metritis.

Dr. Kelly considers the indications in this case so well defined and new that he designs making it the subject of a more detailed critical communication. The patient, about thirty-five years of age, had raised five children, but for several years had suffered from constant soreness of the whole hypogastrium, a spot of intense burning pain to the left of the uterus, and a constant dark leucorrhœa. The menstrual congestions greatly increased her symptoms, which were again aggravated by several early abortions. She had been under excellent treatment before coming to Dr. Kelly, and had been carefully treated by him, but with only moderate, temporary improvement. Dr. Kelly then decided to stop the menstrual function with a view to checking the periodical determination of blood to the uterus, and finally bringing about complete involution of the organ. The operation was performed on the same day as that before described. The ovaries and tubes were removed through an incision two inches long. The ovaries were full of pea-sized follicles, and were covered with a dense capsule, and were, probably (not, however, in consequence of these appearances) diseased. The speaker insisted that the operation here had no reference, whatever, to any disease which might be found in the appendages, but the sole indication lay in the state of the uterus; the ovaries, whether diseased or not, were removed to correct that trouble. The recovery was as perfect and free from disturbance as any slight injury, and the patient was up in the next room on the fourteenth day, when the uterus was free from tenderness, and already rapidly undergoing involution.

Dr. Harris considered the parovarian cyst interesting on account of the character of the fluid, which was opaque and quite as thick as is usually found in ovarian cysts.

Dr. Chas. Meigs Wilson considered oöphorectomy a resort of doubtful propriety as a remedy for metritis; for, as the menopause occurring physiologically would not stop such an inflammation, we would scarcely expect it to be of greater benefit when the result of an operation. He doubts the moral right of exposing the patient to the risks of abdominal section for such a condition.

Dr. Kelly remarked that one reason for the operation for the relief of metritis was the exacerbation of all the symptoms at the menstrual period. Maternity could not again be accomplished in consequence of

abortion; complete rest in bed had failed to stop them. He thinks these ovaries are diseased; ovaralgia has undoubtedly some anatomical basis, but he is not able to say how it is to be discovered; more microscopical research is needed. The history of this case excluded syphilis.

Dr. Joseph Price read

A Report of Thirty-one Cases of Intra-abdominal Operation Done without any Selection in Private Hospital, by Dr. R. Stansbury Sutton, of Pittsburgh, Pa.

October 27, 1883, Mrs. B., ovariotomy; large cyst; recovered.

November 18, 1883. Mrs. O., ovariotomy; large cyst; recovered.

December 28, 1883. Mrs. C., ovariotomy; large cysts; extensive adhesions; tapped frequently; recovered.

February 2, 1884. Miss T., supra-vaginal amputation of uterus with both ovaries and tubes; recovered.

February 20, 1884. Miss P., supra-vaginal amputation of uterus with both ovaries and tubes; large fibroid of uterus; recovered.

March 20, 1884. Mrs. K., ovariotomy; left ovary large and cystic, developed under the broad ligament and roofed over by it. The ligament was opened up to get at it. On right side a fibro-cyst of the uterus with adhesions existed. Performed supra-vaginal amputation of the uterus with the remaining ovary and tube, and split the broad ligament of the left side. Recovered.

April 22, 1884. Mrs. S., ovariotomy; large cysts; extensive adhesions, especially to the liver; had been often tapped. Liver was burned with cautery iron over strip one inch broad by four or five inches long to stop bleeding. Incision in abdominal wall seventeen inches long. Recovered.

May 12, 1884. Mrs. D., large sarcoma of left ovary; general chronic peritonitis with ascites; tumor fed by enormous vessels, Pedicle tied and dropped, as in ovariotomy. Pulmonary clot occurred on fourth day suddenly, with temperature 99°. Died.

May 29, 1884. Mrs. G., ovariotomy; large cyst; adhesions. Recovered.

June 24, 1884. Mrs. S., pelvic abscess. Tait's operation. The pus was stinking. Recovered.

July 12, 1884. Miss M., removal of subperitoneal fibroid; anterior wall; pedicle short. Recovered.

July 12, 1884. Miss L., supra-vaginal amputation of uterus with sixteenth fibroid; extensive enucleation; adhesions numerous. Died.

September 16, 1884. Mrs. R. (insane), removed both ovaries and tubes. Cured; recovered.

September 22, 1884. Miss J., both ovaries and tubes removed. Died of septicæmia on fifteenth day. (Consultants pronounced it typhoid fever.)

September 24, 1884. Mrs. W., supra-vaginal amputation of uterus and both ovaries, with fifteen pound fibroid; extensive enucleation; vast adhesions; tetanus. Died.

December 4, 1884. Mrs. C., supra-vaginal amputation of uterus for large fibroids; extensive intestinal and mesenteric adhesions, and in the presence of peritonitis; very bloody operation; shock was too great. Died.

December 17, 1884. Resection of small intestines at two points for cure of artificial anus and extensive adhesions of gut; fatal on seventh day from renal hemorrhage. Five stones, one an inch long, were found in the kidneys post-mortem. The points of resection were found with difficulty; the sutures were all covered. (My first and only other resection of intestine recovered, and is living 3½ years since operation.)

March 7, 1885. Mrs. J., ovariotomy; large cysts; extensive adhesions; had often been tapped. Recovered.

April 7, 1885. Miss S., exploratory incision. Recovered.

June 10, 1885. Mrs. L., double ovariotomy. Dermoid on right side. Recovered.

June 27, 1885. Miss H., both ovaries and tubes removed. Recovered.

July 30, 1885. Miss D., ovariotomy; large cysts; extensive adhesions; came in a dying condition; had been tapped very often. Died.

November 18, 1885. Mrs. B., ovariotomy; incomplete small cyst; size of cocoanut. As it was impossible to remove the cyst on account of adhesions, it was emptied, dried out, and lining well mopped with a 5 per cent. carbolic. Recovered, and cyst has not refilled.

November 19, 1885. Mrs. M., oöphorectomy, right ovary and tube, recovered.

November 24, 1885. Mrs. W., double ovariotomy, large cysts, bad adhesions, patient very anæmic and feeble, had been tapped often. Recovered from operation, but died of peri-nephritic abscess three months afterwards.

January 9, 1886. Miss N. G., oöphorectomy, pyosalpinx. Recovered.

March 23, 1886. Mrs. R., oöphorectomy, right ovary and tube. Recovered.

April 3, 1886. Mrs. N., oöphorectomy,

both ovaries and tubes, kidneys contracted. Uræmic poisoning a week after operation, coma. Death.

October 1, 1886. Miss S., oöphorectomy, right ovary and tube, chronic ovaratis and salpingitis, Had to dig the ovary and tube out of a mass of adhesions; bad case. Recovered.

November 20, 1886. Mrs. N., double ovariotomy, removed large parovarian cyst and cystic ovary on left side, and cystic ovary on right side. Recovered.

This list of thirty-one abdominal sections are all I have made in my private hospital during the three years of its existence. I have never used spray over a wound, and only occasionally in my earlier cases, I used 2½ per cent. carbolic solution over the instruments. Long ago I quit this, and have used no chemical during the operations. After closing the wound, I am in the habit of dressing it with iodoform gauze. Our wounds all heal by first intention. A great many of these patients had neither health, strength, or money when they came to us. Rich or poor, all have had the same chance for life. All the provisions of cleanliness known to science and art are practiced in my institution. With our present good condition, I believe we can save 98 per cent. of ovariotomies sent within a year or eighteen months from the time the disease begins, and without having been tapped. We never lose a case if in fair condition and if no trocar has been previously introduced into the cyst.

In this list there were thirteen ovariotomies for large cysts, and in one case a supra-vaginal hysterectomy was also done. Of these thirteen cases two died, one of the two three months after operation, and the other was in the last stages of exhaustion, when she was brought in on a stretcher.

Of the cases of supra-vaginal amputation of the uterus and both ovaries there were six. In one an ovariotomy was also done for large cysts. Of these cases, three recovered and three died.

The Tait operation for large pelvic abscesses recovered.

The intestinal resection was not lost through the operation. The removal of the uterine appendages shows a mortality of two cases; one was due to operation, I think, the other was not.

I am sure that, as we gain experience in further operative work and exercise more care in rejecting cases with bad kidneys, our results here will compare favorably with others. Thus far we have refused no patient willing to enter the list for operation, and I am sure that no operator, east or west, is likely to meet with worse cases than are contained in this list.

Summary.—Ovariotomies, McDowell's operations, 13.

Oöphorectomies, Hegar-Tait operation, 8.

Laparotomy for pelvic abscess, Tait operation, 1.

Resection of intestine, 1.

Removal of large solid sarcoma of ovary, 1.

Supra-vaginal amputation of uterus and both ovaries, 6.

Exploratory incision, 1.

Removal of sub-peritoneal fibroid of uterus, 1.

(One case is counted twice: first as an ovariotomy for large cysts complicated with supra-vaginal amputation for fibro-cyst of uterus; second, as a supra-vaginal amputation of uterus complicated by ovariotomy.)

In looking over my ovariotomy cases who have recovered during the last ten years, I find that eight children have been born to them. My last laparotomy (46th), for all diseases yet attacked by operation by me, was a large parovarian cyst, with both ovaries cystic. The cyst and both ovaries were removed through a two-inch incision, the dressing completed, and the woman in bed in thirty minutes, without any haste. She has taken no drugs—not a drop of anything. Temperature on the fourth day was normal, and pulse 76. Wound completely healed. Experience with honest precautions coupled to a possibility of earlier operations and a discontinuance of tapping, will result in as good statistics in this country as abroad.

Dr. H. H. Kelly remarked that Dr. Sutton's account of his cases is very interesting, and in many particulars instructive, and better results for general work, handling all classes of cases without selection, certainly cannot be found in this country. He, Dr. Kelly, called especial attention to the note by Dr. Sutton that his ovariotomy patients have borne eight babies within the past ten years. This fact is significant as deciding a question which has been discussed in terms of vague generalization and sentimentality, "The other ovary."

About a year ago, when writing a paper upon ovarian cysts of large size, Dr. Kelly found facts in Sir Spencer Wells's table which determined this question for him upon a solid scientific basis. Of Sir Spencer Wells's 1,000 cases, 768 recovered, and deducting from these 343 over 40 years of age

as beyond the child-bearing period, we have left 371; again deducting 20 more, which was about the number of double ovariotomies under 40 years recovered, we have left about 351 women survivors with one ovary and in a child-bearing condition. As an actual fact, 117, or about one-third, did bear children to number 228, or a fertility of about 65 per cent. to the total number of survivors. This is then clearly the advantage of leaving one ovary in 351 women, to wit, 228 children. Now what are the disadvantages? Obviously a return of the tumor in the other ovary, and death from the second operation.

In seven of these 351 women a second operation was necessary, and one of the seven died of a tumor, doubtfully uterine.

Here, then, is the status of "the one ovary" case. *One doubtful death* of a woman seven years after her first operation, against *two hundred and twenty-eight children born!*

Dr. Kelly could not accept the diagnosis of death from typhoid fever in a surgical case within three weeks of operation, in the absence of careful post-mortem examination. The typhoid condition is so common in all cases of peritonitis tending to a lethal end, and true typhoid fever so extraordinarily rare, that he rejected the diagnosis not subsequently confirmed. It savors too much of the many cases of women coming to my office, week after week, who tell me they "have never been well since their last confinement, when they had typhoid fever." Dr. Sutton, however, does not himself make this assertion.

Dr. Coffee, of Pittsburg, drew attention to a case under his own observation, in which typhoid fever of distinct character followed close upon a surgical operation.

Dr. M. Price spoke of a case in which typhoid fever followed immediately after an attack of small-pox.

Dr. Joseph Price reported a case of

Hysterectomy for Myoma.

The patient had applied to Dr. J. R. Haynes on account of menorrhagia with hypogastric discomfort. Uterus about the size of a three months' gravid uterus. She became very much prostrated, and suffered from sciatica in the right leg. The tumor grew rapidly, and seven months after first seeing her the tumor was found to extend from the umbilicus to the perineum, resembling in shape and position the gravid uterus at seven months. Two inches below the umbilicus, and to the left, a bruit was distinctly heard. Fœtal heart sounds could apparently be distinctly heard beating 125 per minute, but they were synchronous with the patient's pulse. The lower position of the tumor extended into the vagina almost to the perineum, and resembled very much a fœtal head surrounded by a small quantity of fluid. The os uteri could be felt only with the utmost difficulty behind the center of the os pubis.

November 19th. Dr. J. Price performed abdominal section; before operation her pulse was 150, and temperature 100°. Six syringefuls of brandy were given hypodermically. The operation lasted about an hour. The patient slept well that night, and improved in condition for a few hours, after which vomiting occurred, followed by great restlessness, pain, and increased frequency of pulse. Peritonitis developed, and the patient died at 7 a. m., about thirty-one hours after the operation. Post-mortem examination showed nearly a pint of bloody serum in the peritoneal cavity.

Dr. Price remarked that in reviewing the operation he felt that, with one exception, he had nothing to regret; but he did regret that he had not introduced a drainage-tube; his reason for not using it was the complete absence of bloody stain in the last abdominal washings; but it is his rule to use a drain whenever there have been adhesions to separate; he had three tubes in use in other patients at that very time; he feels assured that if he had used a drainage-tube in this case the woman would have recovered.

Dr. H. A. Kelly considered the important error in this case was the neglect to insert a drainage-tube, and gladly made this subject the text of a few remarks. Operators at large should by this time have reached a common understanding as to just how and when the drainage-tube should be used. In the *first* place: Whenever there is any denuded area as large as the palm of the hand, or smaller, if there be a tendency to weep, a tube should be introduced, and sometimes when least expected several ounces of serum will well up through the tube daily, and the absorptive powers be saved a severe tax. *Seoond: Whenever in doubt, use the tube;* no harm ever comes from it when guarded with the antiseptic precautions now in common use.

His own plan is as follows: Pass all the silkworm sutures as if the whole length of the incision were about to be closed, slip in the drainage-tube (he prefers a straight glass one under ordinary circumstances), and run down the shot and close the wound to the tube; but the two sutures

passing through the track of the tube are left long, to be used after removal of the tube. He then once or twice a day draws out all serum accumulated in the pelvis by means of a long-nozzle uterine syringe; when all discharge has ceased, provided it has been but sweet, clean serum, he withdraws the tube, and running the shot down on the two unused sutures, closes the wound perfectly, leaving only a linear cicatrix instead of a deep pit at the lower angle to be filled up by granulation, and a large plug of scar-tissue; this is also safe after suppuration, provided all suppuration has entirely ceased.

He does not like Kœberle's clamp, which had been used by Dr. Price in this case, and considers it far more dangerous in every way than the elastic ligature. Särgen's device, just announced, combining an extra and intra peritoneal treatment, promises much, and is certainly destined to repeated trial.

Dr. Montgomery thought the case one of extreme interest in point of diagnosis and treatment. The pressure of the tumor on the uterus causes changes in them, and also sacculation of the kidney. He had operated in a similar case some years ago, and subsequent examination revealed sacculated kidneys and pus in one; even if no knife had been used, the patient would have died from the ether. He thinks with Dr. Price that the drainage-tube should have been used in his case.

Dr. Joseph Price remarked that he had no fear whatever of the drainage-tube, and thought it might he used in every case. Tait's rule, "when in doubt use the tube," was a good one. Dr. Price made some remarks upon his method of using drainage-tubes of glass, using cotton wick in some cases to remove accumulations of serum and to clear the openings of the tubes, using a sucking bulb with gum tubing to draw out fluid accumulations, and introducing a smaller gum tube through the glass one before withdrawing the latter.

Dr. M. Price exhibited specimens from a case of

Pyo-salpinx

of gonorrhœal origin. Is pyo-salpinx not generally or always the result of gonorrhœa? His cases have, without exception, followed attacks of gonorrhœa. Can such a sequel be anticipated and prevented?

Dr. Montgomery remarked that Dr. Noeggerath initiated the idea of latent gonorrhœa as the cause of salpingitis and pelvic peritonitis.

Dr. M. Price remarked that his patients had been in robust health; they were generally women who had born but one child, and the labor had been followed by repeated attacks of peritonitis.

Dr. Longaker read a report of a case of

Laparotomy for Pyo-salpingitis.

Maggie T., aged 33, was admitted to Lying-in Charity Hospital, November 13, 1886. She had one child 18 years before, after a difficult and prolonged labor. Unmarried, and has a history of specific disease. During the last four years her periods have been accompanied by intense suffering, and in the intervals she was never free from distressing aches in the pelvis. Lately she had used opium to some extent. In addition to the evident enlargement of the appendages on both sides the patient has a perineo-recto-vaginal fistula and a stricture of the lower end of the rectum. A diagnosis of pelvic cellulitis was made by him in this case two years ago.

Operation, November 18. The left tube, a sausage-shaped tumor, and the ovary, a fluctuating mass the size of a walnut, were easily removed; a small amount of pus escaped from the end after ligation, and this was arrested by pressure forceps. The ligature was necessarily passed near the uterus, but owing to friability of tissues, troublesome oozing continued, and delayed the closure of the abdomen. On the right side the ovary and tube formed a huge abscess, the size of a goose-egg. It was impossible to separate and remove this without rupture. It was filled with pus and altered blood. Adhesions were dense and firm. There was also some oozing on this side, but it gave rise to comparatively little trouble. The peritoneal cavity was irrigated with hot water; 1 to 5,000 bichloride solution on sponges. Abdominal walls sutured with silk, over which was placed an impervious coat of iodoform collodion. Convalescence uneventful. She is now free from pain.

Dr. M. Price inquired about the source of hemorrhage. He had seen serious hemorrhages due to the fact that the tube was cut by the ligature. He thought it important to tie straight across the tube and not obliquely. He ligates by double ligature and ties back. He considers it right to open up at once if hemorrhage is at all free; he does not think it right to trust to sponges and hot water.

Dr. Joseph Price had seen very free hemorrhage from adhesions to the bowels, large sinuses being laid open and pouring out blood. In several cases he had used iron as a styptic.

Dr. Longaker explained that the hemorrhage came from the opening up of the broad ligaments.

Dr. H. A. Kelly read a paper embracing

Notes on Palpation of the Female Uterus,

which will be published in full with diagnosis.

Dr. Joseph Price read an interesting letter from Dr. Joseph Eastman, summarizing the features of McDowell's early operations, showing how perfectly antiseptic his work was.

Dr. Coffee spoke of Dr. Sutton's work as being pioneer work. He gave up good practice and went to Europe to work up this field.

General Neuroses having an Ophthalmic Origin.

Dr. H. Bendelack Hewetson thus writes in the *Lancet:*

It is now some years since I first observed symptoms, many and varied, occurring in neurotic persons who were also the subjects of uncorrected optically defective sight. In investigating more particularly the relationship between the various optical errors and sick headache, or simple headache, I was occasionally startled by the apparent direct relationship between the long uncorrected disorder (with all its immediate train of nervous disorders) and general conditions of ill-health which seemed to be the direct outcome of a thus already demoralized nervous system. It is now well established that many cases of migraine or sick headache are directly attributable to the reflected irritation of the brain (and thence the gastric functions and heart's action) from some uncorrected optical state, chiefly on the side of hypermetropia, and always in a neurotic subject. It is also well proven that many of these cases are entirely relieved from their periodic attacks by the use of properly-selected glasses; or, having passed an age when the activity of the accommodation ceases more or less, and the eye becomes presbyopic, the severity of the headache or migraine becomes greatly modified. It is further well known that a patient the subject of hypermetropia is liable, according to varying circumstances, such as extent of defect and use of the eyes, to more or less constant "head pains," not necessarily associated with very obviously defective vision or aching eyes, but always peculiar in their position and character, and aggravated by close application of the sight. Although I have very fully published my observations some time ago on the relations between sick headache and optical defects, and utilized what was previously discovered as to the relation between headache (broadly defined as such) and hypermetropia, I had not felt my footing sufficiently to enable me to bring forward that which it is now my desire to show—viz., that the neuroses growing and arising from congenital optical error are more subtle in their nature, more varied in their distribution, and more demoralizing to the right evolution of the nervous system, than I was at first led to suppose.

The most common forms of headache associated with that optical error known as hypermetropia are—either simply a heaviness or pain over the brows (this may or may not be combined with general headache), or very frequently a tender place on the top of the head, making it particularly painful to dress the hair—such a pain as occurs after a lock of hair has been "slept on the wrong way," in common parlance; there is also frequently pain at the back of the head. All these pains may be present together, or they may exist singly, but they all occasionally occur in conjunction with severe neuralgia at the back of the neck. This I have frequently noticed, and where it occurred, whether associated with the other head pains or not, it, as well as they, soon disappeared with the systematic use of accurately adapted correcting glasses. This symptom of pain at the back of the head and neck is not one which has long been associated with optical defect, but I have now seen a sufficient number of cases to show without doubt that such may be safely regarded as one of the symptoms of (frequently latent) optical error, perfectly remediable by the use of glasses, and, when such, by glasses only.

Dr. Lauder Brunton writes me that he has seen several cases of neuralgia of the back of the neck cured by glasses. It would not appear to need demonstration that with symptoms so severe and depressing to the

general nervous system as are the various forms of headache—vertigo, which is associated with astigmatism, vomiting, possibly, as I have noted, palpitation, or neurotic dyspepsia between the attacks of migraine—other conditions should arise as a sequel in many constitutious. One which I particularly wish to draw attention to is insomnia. This particular symptom I observed in one or two cases, the subjects of astigmatism. In one instance in particular, where the eyes had given much trouble during the examination period of an Oxford man's life, it was particularly remarked to me that after the astigmatic trouble was corrected by suitable glasses, *with an equal amount of work*, the insomnia disappeared and the whole physical and nervous state of the gentleman improved greatly. One object of my paper will be to show what an important factor these optical errors are in, as it were, moulding during childhood and early life the nervous and constitutional state of the individual. As a proof of this I will quote two cases, both in ladies of education and refinement, which seem to give us some sort of clue to the possible effects on the constitution of persons who conscientiously struggle through a severe scholastic career with important optical errors entirely uncorrected.

The first case was that of a lady aged twenty-two, whom some few years ago I found to be the subject of confirmed hypermetropic astigmatism. Her health was not good, but she particularly complained of headache and general feelings of malaise. I corrected the astigmatism after very patient testing, since her great nervousness made it a very trying process for myself as well as the patient. There were other symptoms such as would be ordinarily covered by the convenient but too easily accessible term hysteria, which showed itself in subjective pains at the back of the neck, tenderness of the spine, and frequently of the skin generally. There was no apparent lesion in any important organ, and she appeared to be the possessor of a greatly-demoralized nervous system, which was easily overwrought, no matter what amount of moral pluck appeared to be put forth to resist an attack. After wearing the glasses for three years constantly her whole being seemed to change, so great was the relief. All headaches and difficulty in obtaining sleep disappeared, the appetite improved, and she became more companionable at home. But there was evidently, with all this improvement, a disordered state of the nervous system not yet removed, the tenderness of the spine remained more or less, and the health was still subject to variable and unaccountable fluctuations. I made up my mind that though the head pains had been so far recovered by the use of glasses, yet the long struggle in pain and toil of educational work had so far damaged the peripheral nerves that some other means of cure must be attempted. I may say that drugs had long since been given up as useless. It occurred to me that a course of medical rubbing would probably be productive of some good in the form usually called "massage." I accordingly sought and obtained a consultation with Dr. Fletcher Little at Ben Rhydding, in the early part of last winter, and, although the weather was so severe, we decided that the patient should undergo this treatment under Dr. Little's supervision at Ben Rhydding, and I have greatly to thank that gentleman for assisting me to obtain the excellent result, for in two months she went home perfectly well, and I may also add she remains so.

I have in the second case received great encouragement from the treatment above adopted, but its expense necessitated an early abandonment of the massage, yet I have heard that the patient is much improved in general health.

I could multiply instances in which varying degrees of this kind of nervous demoralization occurred; but generally there is either nerve-resisting power or neurotic recuperation sufficient to enable the individual to recover, if the sight be fully corrected, without having to resort to the massage treatment for the rest. I am perfectly convinced that until the sight had been corrected all such treatment as I have indicated would be useless. If carefully looked into, this appears to me to suggest some very important conclusions in relation to the community at large. I see children driven to do their work although suffering from defective sight, constant headache, and restless nights, which result in great exhaustion of the nervous system, disturbance of the various functions of the body, and a disinclination to innocent and beneficial child-play, all of which is with perfect ease set to rights by a correction of the optical defect which causes it. But supposing that a naturally nervous subject grows up under these conditions, the right evolution of some of the nervous system is undoubtedly endowed with morbid action, as well as the formation of the character disturbed. The causes are evident; the consequences, I believe, will be found in some of the neuroses which I have endeavored thus imperfectly to describe. As

the practical outcome of these observations, I trust it may not be considered a superfluous precaution to suggest that all children's sight should be tested by the ophthalmoscope before they commence their educational career.

A Case of Angina Pectoris.

Dr. Louis Asta-Buruaga thus writes in the *N. Y. Med. Jour.:*

In looking over the history-books of the Roosevelt Hospital, I was struck with the fact that since the opening of the institution (1871) only two cases of angina pectoris had been registered therein, in both of which the patients had been discharged improved, and in at least one of which no mention was made of an attack occurring while the patient was under observation; neither was the sense of insecurity of life, so essential a symptom in angina, noted. This lack of cases of angina pectoris in the records of the hospital seems to accord with the statement generally made as to the extreme rarity of such cases in hospital practice. Dr. Walsh says that "a solitary well-defined example of true angina" had come under his notice in his wards.

The fact that this cardiac neurosis seems to be a disease of the well-to-do classes, who, as a rule, strongly object to post-mortem dissections, may be a reason why so few necropsies of the malady are contributed to medical literature. Having read the pages of the *New York Medical Journal* for the last two years, I do not remember having met in them with more than one account of an autopsy held upon a patient dead from angina pectoris. This only case was reported by Dr. G. R. Butler before the Brooklyn Pathological Society, and published in the *Journal* of July 10, 1886. The lesions there found were very similar to those of a case observed by me at the Roosevelt Hospital, a report of the symptoms and pathological changes of which I here give in detail:

The patient, a man aged forty-six, and a native of France, was admitted to hospital on the evening of May 28, 1886. He gave on admission the following account of himself: For the past five weeks he had been suffering paroxysmal attacks of pain, which originated in the right half of the mid-sternum, from there shooting backward to the dorsal region, upward to both shoulders, and occasionally, together with a feeling of numbness, down both arms. The pain is of a sharp, stabbing character, and "takes the breath away" from him. While it lasts he has a feeling of oppression about the chest, his breathing becomes labored, and he is seized with a fear of impending death. During the attack he perspires freely. Occasionally the paroxysm is attended with eructations of gas from the stomach and vomiting, or one or the other of these symptoms singly. At no time did he lose consciousness, nor did he fall to the ground. At the onset of his illness the cardiac crises took place from two to three times a day, and individually lasted from fifteen to twenty minutes. Of late the bouts have been increased to five or six a day.

The patient's mother had been subject to anginoid attacks. The patient himself had never had rheumatism, nor had he evidences of previous cardiac, pulmonary, or nephritic disease. He gave a history of syphilis, having contracted the initial sore twenty-five years previously; and he confessed to the alcohol and tobacco habits.

The man was well-nourished, and, though his countenance was rather pale, his mucous membranes were ruddy, and his tongue was red, moist, and clean. His appetite, he said, was small, his bowels were torpid, but he passed his water well and in good quantity. His pupils appeared normal. The heart action was feeble, the cardiac sounds were muffled, and no murmur was audible upon auscultation. The pulse was small and somewhat rapid—96 to the minute; respirations hurried—40 to the minute; temperature, 98° F.

Shortly after admission, 8:30 p. m., the patient was seized with a severe attack of pain and great distress about the chest. He sat up in bed, and leaning forward upon his unbent knees, clasped his bosom firmly with both hands. He seemed afraid to breathe, and held his breath, this cessation of the respiratory act being followed by labored and deep respiration. His face was deathly pale, he looked anxiously about him, yet dared not cry out for relief. His whole frame was moist with clammy sweat, and his extremities were cold to the touch. The radial arteries felt hard and cord-like, and the blood-tension was apparently heightened. The heart action was tumultuous and rapid, beating 112 to the minute. At the end of this attack the patient vomited profusely, and complaining of faintness, he fell back on the pillow, almost on the verge of syncope.

Hardly had he emerged from this paroxysm, which was of a few minutes' duration, when he was attacked by another similar one. Nitrite of amyl was pushed to its full physiological effect—flushing of the face

and softening of the pulse—without giving ease. Six minims of Magendie's solution abated the pain, but at the end of an hour, 10 p. m.. the patient was taken with cramp in the belly, without any thoracic distress, which called for another hypodermic of morphine for its relief. At about 1:30 a. m. of the following day, he arose and walked across the room to the bath-room. At a few minutes of 3 a. m. he was found in his bed dead and cold.

At the autopsy, made by Professor Delafield ten hours later, the following appearances were found:

Rigor mortis unusually well marked, most of the voluntary muscles strongly contracted.

Brain not examined.

Lungs fully inflated, lower lobes somewhat congested and œdematous. Heart-walls relaxed, cavities distended with red and yellow clots. Left ventricle somewhat dilated, and its walls thinned. Aortic valves thickened and insufficient. Mitral valves a little thickened.

The aorta showed patches of chronic endarteritis along its entire length. Just above the aortic valves there was a large, deep patch, partly calcified. This patch involved the openings of both coronary arteries, narrowing them very decidedly, but beyond this point the walls of these arteries were normal, and they contained no thrombi.

The liver, spleen, and kidneys were congested.

A Practical Hint on the Performance of Tracheotomy.

Dr. W. Leonard Braddon thus writes in the *Lancet:*

Upon looking through various text-books and articles upon this operation I can find nowhere any insistance upon the following detail—one important, as I believe, at any rate to operators of not large experience, and valuable, as increasing greatly the facility, and therefore the success, of the operation. The operator is usually recommended, standing preferably on the right side of his patient, after first determining the exact relation of the parts, to fix the trachea with the left hand, the fingers on one side and the thumb upon the other, at the same time stretching the skin at the site of the incision. The direction is at least distinct, but the manipulation is in effect usually very different. In all of many cases which I call to mind there has been a little (the only) trouble in the operation, and in some, considerable danger, delay, or anxiety, consequent upon the way in which the attempt is made to keep the windpipe steady, as customarily taught and performed; four fingers on the left side and the thumb upon the right side of the larynx press with more or less force immediately backwards to hold the organ in place, with the effect of considerably aggravating the dyspnœa (especially if an anæsthetic is not being employed), of flattening the pipe against the vertebral column to some extent, of in all cases increasing the depth at which the part to be incised can be reached, and frequently of failing to secure fixity of the larynx, which, likely to move with the slightest change of pressure, is pushed still more out of reach by the increased pressure made to secure it. Any or all of this inconvenience is the result of pressing backwards with the fingers placed upon the skin immediately on either side of the windpipe.

The suggestion I have to make, and which, I have no doubt, many surgeons have long ago thought of or adopted, although hitherto I have never seen it noticed, is so simple as to provoke a doubt as to its value; but any one who tries it will, I think, find it so effectual in practice as to have no more doubt than I have as to its advantages. Let the surgeon place his left hand, as widely expanded as possible, over the neck of a child in the position for tracheotomy, then resting the fingers upon one and the thumb upon the other side firmly upon the skin, as far to the side of the neck as they will reach, gradually draw in the thumb and fingers, and the skin (and loose tissue underneath) with them, towards the median line; as the sides of the windpipe are approached, a little more pressure, made in a backward direction, will place the ends of thumb and fingers in a position in which they almost meet behind the larynx, which is thus firmly held by the encircling hand in a position in which all the great blood-vessels, etc. (which *have* been wounded), and the vertebral bodies (which, it is recorded, have *blunted a knife-point*) are far out of harm's way, the windpipe itself starting forward and standing out prominently under the skin, which is yet fairly stretched (and can be stretched more tightly) over the site of incision, and lying both as superficially as could be desired, and as perfectly under control as possible. Lastly, and this I think is not altogether unimportant, this procedure may be adopted without producing more than the very slightest degree of discomfort in any ordinary child—the younger the more easily; and one is still able to make the skin as tight as possible; now,

however, the necessary pressure is distributed all round, instead of acting directly backwards upon the tube so as to flatten or displace it. I have even been able, without much trouble, to make the thumb and fingers feel each other behind it by this means; while by the older methed I have seen the production of undoubtedly a dangerous increase of dyspnœa. I may have overrated the danger or underrated the utility of the usual method of fixation, but it has always seemed to me to be the only difficulty in an operation which of course has none for experienced surgeons, but to others presents often some trouble, chiefly in consequence of the fact that the means adopted for fixing the part to be incised, being ill-devised though time-honored, are not only not to be relied on to secure that end, but, as I have tried to show, they directly tend to increase the depth of the wonnd of the trachea from the surface and the distress of the patient; and in all the accidents I have read of, and some that I have witnessed, this method has shown itself marked sometimes by danger, often by inutility. As to the barbarity of the *hook*, is it not an insult to the fingers of the χειρουργός?

Small versus Large Doses of Medicine.

Dr. J. K. France thus writes in the *Pacific Med. and Surg. Jour.:*

The advancement of medical science during the last half of the present century has been marked, particularly in the departments of materia medica and therapeutics. The improvement is striking as regards new articles introduced, and in the quantities and modes of administering those long known to the profession. The ponderous doses so commonly prescribed thirty or forty ago, are superseded by much lighter ones in more agreeable forms and by hypodermic medication. The heroic treatment practiced at the beginning or middle of the century has scarcely anywhere an advocate.

The *vis medicatrix naturæ* and the certain, controlling powers of medicine are becoming better understood. The disastrous effects of large doses, especially of heart sedatives, in depressing the vital forces and causing death in many cases, are justly looked upon as *murder* perpetrated by licentiates of our profession. Doses comparatively *very small* when frequently administered at short intervals are safer and more successful, and are being much used by intelligent practitioners. Even our systems of mental philosophy and the powers of the mind in their application to the treatment of nervous and all forms of disease are becoming more recognized by every worthy disciple of Hippocrates.

As typical cases that distinguish the present time, we cite the example of Ringer, of New York, who prescribes as anti-bilious purge, calomel, one-half grain; extract of hyoscyamus, three grains; to be mixed, and the dose repeated for three nights in succession, assisted by a few drops of the tincture of nux vomica. For a similar case the physicians of thirty or forty years ago would have prescribed calomel, twenty grains; jalap, twenty; to be mixed and given as a single dose, assisted or preceded by the abstraction of a pint or two of blood. In all inflammations it was customary practice to *bleed*, in many cases to the extent of syncope; also to apply blistering cerates covering many inches or a foot of surface.

But as science progresses the ideas and practice of a former age have changed, and many prescriptions are now made, consisting of a single drop or grain, or part of a drop or fraction of a grain, for a single dose. Morphia, usually given in the one-sixth of a grain, is now prescribed by many in much smaller quantities. It acts better in a vast number of cases when administered in the fifteenth part of a grain, repeated at intervals of half an hour or hour, operating without nausea or wakefulness, often the result of large doses. Calomel given in the tenth part of a grain, or even smaller quantity, repeated hourly for several hours in succession, produces better results than in the larger doses, causing little or no nausea, but all the good effects that belong to this invaluable medicine. The tincture of aconite has a greater effect in controlling arterial excitement and fever, given in one-fourth drop doses every hour, than two-drop doses every two hours. By its use in these small doses we can secure all the sedative effects we wish, and, what is greatly to be considered, without causing depression of the vital powers, a fact of great importance in making prescriptions of so potent a remedy.

But it is not morphine, calomel, or aconite alone that are more curative in *very small* than in the usual, comparatively large, doses. The doses of our whole catalogue of medicines, as given in our standard authorities, need to be reduced in quantity. A radical change in this respect should be made to keep pace with a more benign and enlightened therapeutics.

It is curious that comparatively very small doses act better than large doses, but experience confirms the fact. The more frequent

reception into the stomach may cause a more constant medicinal effect upon the vascular and nervous functions. The absorbents may receive more kindly the small, almost homœopathic doses, while the large ones excite, and thus prevent the assimilation of the medicine into the blood. Our materia medica needs revision, and our therapeutics will undoubtedly be improved and changed in the future. We need in medicine more of the certainty and exactness that should belong to so grand a science. The field in this respect is large and the need is great.

Two Severe Cases of Chronic Dysentery.

Dr. W. H. Lang thus writes in the *Edinburgh Med. Jour.:*

The following notes on two severe cases of chronic dysentery may be of interest and value to some who may be driven to their wits' end, as I was, in giving relief to intractable chronic dysentery.

Case 1. Mr. J. S., aged 28, had been suffering for five years. The disease was contracted in Fiji, and he had been under a large number of doctors since then. Each one had promised him a rapid cure, and he had obtained benefit for a time from half-drachm doses of ipecacuanha. The last medical attendant (a homœopath) had told him that he was suffering from internal piles. On examining him, I found all the organs healthy, and could see or feel no trace of piles. There had been phthisis in his family. The motions were composed of a bad smelling jelly-like substance, mixed with a considerable quantity of blood. They numbered from eight to ten per diem.

I determined to persevere with sulphate of quinine, alternating it with liquor ferri pernitratis, as the disease had been contracted in a malarious climate, and he is very anæmic. He also used injections into the bowels of hazeline, thrown as far up as possible, and wore a water belt for several hours a day. From this treatment he obtained no relief, and as everything else seemed to have been tried, I felt somewhat despairing. My attention, however, was called to an article in an old number of "Braithwaite's Retrospect," recommending potas. nitratis for a case of this kind, and I at once tried it, giving the following three times a day before food:

℞.	Potas. nitr.,	grs. xxv.
	Sp. chloroformi,	♏xx.
	Liq. opii sedat.,	♏viij.
	Sp. æther. nitrosi,	♏xx.
	Aq.,	℥j.

On the second day the motions were reduced to six, the third day to three, and since then, for over a month, there has only been one, or at most two, good healthy natural motions. In fact, at one time I had to order him cascara sagrada, as the bowels became too confined, although the opium had been removed from the medicine. All this time he was on a plain, bland diet of milk, milk-puddings, eggs, and fish. He has gained greatly in weight and strength, and is as ruddy as David was.

Case 2. Miss L. K., aged 25. Two and a half years ago caught a bad cold, and dysentery hod commenced and never left her. Her doctors had given her up, saying no medicine could do her any good.

All her organs were apparently healthy; family history good. Menstruation had ceased from the first. She was very anæmic. Motions typically dysenteric, and very bad smelling; twelve or thirteen during the twennty-four hours. I put her on liquor ferri pernitratis, and persevered for three months with it, during which time the motions became reduced to four or five per twenty-four hours. Menstruation commenced, ond she gained splendidly in weight. I now tried the potass. nitrat., having met with such success in the previous case. But here disappointment awaited me. The motions became more frequent and bloody, menstruation ceased, and all the previous advantage was lost. Why this should have occurred, I am at a loss to understand. I am now, by one-drachm doses of ipecacuanha, endeavoring to allay the exacerbation, and shall then return to our old friend, the liquor ferri pernitratis; but it is somewhat puzzling why the one medicine should have acted in the one case and failed so entirely in the other.

Natural History of Tuberculosis and the Bacilli Theory.

Dr. R. B. Davy, of Cincinnati, has lately read two papers before the medical societies of that city, in which he thinks he has shown the infectious theory of tuberculosis to be supported in every respect by the natural history of the disease. He does not lay particular stress on the "bacillus tuberculosis," and speaks of the poison more as the "tubercular virus," but insists that, like all other organisms, it is a creature of heat and moisture. From the fact that its appearance and extension are only noticed to occur in confined spaces, and its disappearance most favored in unconfined spaces, he concludes that the danger of infection depends more upon quantity than quality of poison. After

extensively discussing the natural history and climatic treatment of the disease, he comes to the following conclusions:

I. That tubercular phthisis occurs most frequently and most fatally in warm or hot regions characterized by a non-porous soil and the ordinary accompaniment of excessive humidity of atmosphere.

II. That it depends upon a specific organism, which can be made to produce the disease by inoculation.

III. That the key to the introduction and development of this organism in the system is ordinarily some form of irritation.

IV. That the disease is plainly curable in all its forms except the acute, and even this may not always be fatal.

V. That to the predisposed it is communicable by infection through the medium of a polluted atmosphere.

VI. That the infection depends upon quantity rather than quality of virus.

VII. That on the open sea, where every condition favoring the development of tuberculosis is present, except the presence of tubercular spores, the disease speedily disappears.

VIII. That the nearest approach to perfect immunity from tuberculosis is to be found on high mountains, where, on account of extreme rarefaction and accompanying dryness of the air, the tubercular organism cannot exist.

Mobility of the Heart.

Dr. M. M. Shershevski publishes in the *Vrach* a paper on the mobility or displaceability of the heart. The fact that the heart's position is liable to slight changes according to the position of the body, has been recognized by Bamberger, Gerhardt, Luschka, and other observers, but they have none of them formulated the conditions under which it takes place. Dr. Shershevski gives details of the examination of forty persons, all of them free from cardiac and pulmonary affections, in whom he noted accurately the position of the heart's boundaries in the upright dorsal, left lateral, and right lateral positions. The chief mobility was towards the left side, but the heart was often quite perceptibly displaced to the right, as well as downwards and even backwards. The chief conditions under which this occurred were youth, nervous states, and freedom of the vessels from signs of sclerosis. Displacement backwards was found in nearly half the cases, and this shows that the heart ought to be examined in the upright posture. The writer especially remarks on this when the examination is made as a prelude to the administration of chloroform, whereas, as a rule, the stethoscope is applied when the patient is lying down and in a very agitated frame of mind, which latter condition always renders the organ more easily displaced; and the diminished diameter due to this may lead to erroneous conclusions if the measurements be not previously taken in an upright position. This has reference chiefly to young persons. In the case of subjects over sixty years of age, and of much younger persons whose arterial system had already begun to show signs of degeneration, there was little or no displacement produced in any position.

Reviews and Book Notices.

BOOK NOTICES.

Worthington's Annual for 1887. 1 vol., 4to. Illustrated. Worthington & Co., 747 Broadway, New York.

This pretty and interesting work for the young contains a series of stories, papers on natural history, biographies, and short sketches—just the kind to attract youthful readers. The selections are handsomely illustrated with numerous engravings, many of them of full-page size, and charmingly colored by one of the new processes of color printing. For a holiday gift to the children, it may be commended to all our readers.

Cinchona Febrifuge in India.

An attempt was made last year by the Indian Government to promote the use of cinchona in the Central Provinces of British India, by offering it for sale in small quantities at cost price. This attempt has proved a failure; for in the report of the charitable dispensaries in the Central Provinces for the last year, the Civil Surgeon of Chanda complains that cinchona febrifuge "is a nauseous and very uncertain drug, and dear at its price when compared with quinine. The people are willing enough to use cinchona, if they obtain it gratis; but they will not buy it, even at cost price, except in insignificant quantity. For quinine, on the other hand, there is always an eager demand; and in future the febrifuge will be offered for sale in much smaller quantities than has hitherto been the practice."

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

MIGHT BE IMITATED HERE.

On November 1 the Public Institute of Disinfection, erected by the city of Berlin, was opened in Reichenberger street 66. In this place there may be disinfected clothing, linen, beds, mattresses, straw bolsters, coverlets, carpets, curtains, upholstered furniture, etc. The disinfection is performed by the aid of hot watery vapor, except in the case of such articles as furs, leather, etc., which would be ruined by the steam, and here chemical preparations are made use of. All the articles to be disinfected are brought by men specially employed by the city for this purpose, from the respective residences to the institute; and a number of wagons and horses are kept for this purpose. The same men carry the articles back, and they are instructed to use the utmost care to prevent non-disinfected articles from coming in contact with such as are already disinfected.

To insure still greater safety in this respect, the Institute has two entrances, leading to different parts of the building. These parts are kept separate, and a special officer has to pay attention to the carrying out of this rule. The articles to be disinfected enter by one door, and are brought to the first part of the building. From here a door, kept locked by the officer in question, leads directly to the hall in which disinfection is carried on, and as soon as the articles have been subjected to the hot vapor they are removed to the other part of the building, and from there carried away, passing out of the other door.

As regards the fees to be charged, the following, including disinfection and transportation of goods from the owners and back again, until further notice will be demanded for the work:

The lowest charge will be about 75 cents, then for every cubic meter of space again 75 cents. The calculation is based upon the tenth part of a cubic meter, while for articles which have to be disinfected by chemicals about 20 cents is charged per hour, the chemicals used being extra. Here the calculation is based on 15 minutes.

When so many cases of typhoid fever, scarlatina, diphtheria, and other epidemic diseases occur as in our large cities, the example of Berlin might well be imitated here. These institutions would soon pay for themselves.

NEURITIS CAUSING NEUROSIS.

In the section of neurology and psychiatry of the German Congress of Scientists, held September 24, Dr. Moritz Meyer, of

Berlin, took up the subject of inflammation of nerves often being the cause of neurosis. Not only was the inflammation produced by injuries and other traumatic accidents, but it often passed from neighboring organs on to the nerves, and was also characteristic of certain other diseases, as tabes, diabetes, etc. M. found the lesion in cases of co ordination disturbances due to occupation, then in such of peripheral neuralgias, and in some motor and vaso-motor spasms, as migraine, tic douloureux, and even in epileptic conditions. In all these cases a neuritic exudation could often be demonstrated.

The observation is of importance as indicating an antiphlogistic form of treatment, while as soon as the acute stage has passed, and when not recognized in time, the galvanic, constant current, gave him the best results, though stretching of the nerve also proves of value at times.

Meyer's remarks gave rise to a discussion, which became specially of interest on account of the authorities participating in it; Professors Erb, Benedikt, and Bernhardt being amongst them. Erb cautioned against the the too frequent assumption of neuritis, as the conditions found after death did not verify such such statements as made by Meyer, while Benedikt, though leaning more to Erb's views, expressed himself in favor of the antiphlogistic treatment, which, in many cases, if early resorted to, would prevent chronic neuralgias. He also greatly recommended the points de feu, and ascribed to galvanism far more effect that to massage.

Bernhardt was of Erb's opinion, and remarked that his investigations had demonstrated more frequently the existence of a peri-neuritis, and of peri-neuritic exudations, than of inflammation of the nerve itself. If Bernhardt's view is correct, and it can scarcely be doubted, the good results which are obtained in many cases of neuralgia by blisters would be explained.

OSSIFICATION OF THE SOFT MEMBRANES OF THE BRAIN.

Dr. Meschede has reported two cases of insanity where the pia mater and the arachnoid membranes were both found to be ossified. The first case concerned a young insane girl æt. 19, who had remained for years in melancholic conditions, interrupted frequently by epileptical attacks, in consequence of which she finally died. The existence of insanity in her mother was proved; in her tenth year, after preceding headache, all the hair had fallen out (defluvium capillorum), and in her sixteenth year an acute attack of melancholia developed. The autopsy revealed on the upper surface of the right frontal lobe a bony plate, 1½ inch long by 1 inch wide, which could easily be removed from the cortex, and which, under the microscope, presented the structure of the pia and arachnoid completely changed into bony tissue. At various other places over the same hemisphere smaller bony plates were found distributed, and the soft membranes wanting at their places.

The second case concerned an insane woman, who had occasionally suffered from acute attacks of mania. Here the ossification was far more extensive, and closely adhering on one part to the falx. M. is of the opinion that the pressure produced by the bony plates caused such an alteration in the intra-cranial circulation that it gave rise to some of the symptoms mentioned.

CHOLERA IN GERMANY.

From the *Deutsche Med. Zeitung*, November 14, we obtain the following information concerning an outbreak of cholera in Germany:

Since the end of September rumors appeared all over the continent of Europe that several cases of Asiatic cholera had been observed in the villages of Gorsenheim and Firthen, near Mainz. After these vague rumors had been circulating through all the newspapers in the State, the authorities published a statement denying the presence of the dreaded epidemic. An examination was made, however, November 2, by the Director of the Public Office for Investigations of Epidemics, etc., at Wiesbaden, and he found the unmistakable evidences of the presence of comma bacilli in the intestines of two persons who had died of the disease. As soon as notice of this discovery reached the authorities in Berlin, Koch and his assistant, Gaffky, at once left for the infected district.

This occurred November 13. As the cable has not brought us any news of the further spreading of the disease within the boundaries of Germany, we may presume, until our exchanges shall give us more light on the subject, that the most energetic measures were at once instituted, with the happy result of extirpating the malady, or of at least limiting it to its original locality.

GONORRHŒAL RHEUMATISM.

Dr. A. Frankel (*Charité Annal*, 1886, p. 182,) reports the case of a man, where immediately after the sudden cessation of the discharge in a case of gonorrhœa, acute ar-

ticular rheumatism developed. The case is specially interesting on account of the many points involved—shoulder, hip, knee, ankle, elbow, and maxillary—also because of the long duration of the high temperature and of the complication with sciatica and the inflammation of sinews present in the case. Antipyrin, iodide of potash, and salicylic acid, had almost no influence on the joint affection, only the last-mentioned remedy somewhat ameliorated the patient's condition by diminishing the pain and bringing the temperature down to the normal.

It is peculiar that of late so little progress has been made in this complication of blennorrhœa. The rheumatic affection should always be studied at its start, so that by the aid of a great number of observations certain data might be elucidated. It should be determined whether there always is a cessation of all discharge the moment the rheumatism first appears, for if that question can be correctly answered, we would at least know whether to ascribe this rheumatism to metastasis of the specific poison or not. The theory of pyæmia alone is surely not tenable.

Notes and Comments.

Annual Subscriptions Due.

Our readers will please remember that on January 1st many of their subscriptions fall due for the ensuing year. We trust that they will forward the amount promptly, as this action on their part will increase the efficiency of the management, and save the disagreeable necessity of "dunning" at a later period. We therefore particularly request that *all* whose subscription expires December 31st, will remit as early in January as possible. If bills are wanted, send us a postal card with the request.

The Nomeclature of New Drugs.

A tendency has recently become evident to name new drugs, especially those of chemical orgin, rather in accordance with their supposed therapeutic effect than with their chemical constitution. The names antipyrin, antifebrin, and hypnone, are examples of a practice which cannot but lead to much confusion. If a drug which lowers the temperature in fever is to be called antifever, then we shall have others known as painkillers, or diarrhœa-producers. Further, a drug, originally introduced as a local anæsthetic—aconite, for example—may subsequently be applied to totally different uses. Such a practice, moreover, by stamping a drug with the mark of one description of physiological action, would tend to divert the attention from other and possibly not less important attributes. It would be going back to the *mistura tussis* or the *bolus purgans* of our ancestors. The only rational plan to follow in such cases is to give the newly-discovered compound a name in conformity with, or bearing some relation to, its chemical constitution, as was done in the case of chloroform and chloral. The trifling discrepancies which may now and again arise in consequence of some change in our views as to a particular rational formula would not then be attended with a corresponding inconvenience from a therapeutical point of view.

Pruritus from Carbolic Acid.

Dr. C. Leonard Whitmire records an interesting case in the *Peoria Medical Monthly*. It appears that a young married man, of 25, accidentally spilled some carbolic acid over his shoulders and back. He did not wash it off, and in consequence his shirt became thoroughly saturated with it and an extensive sore was produced. He rubbed goose-grease over the part and thought no more of it. Eight or ten days after the accident, he began to experience strange pricking sensations in the neighborhood of the wound. The severity of the symptoms increased and spread rapidly over the whole surface. This pain became so intense that he kept continually scratching, and finally he could not rest and kept running up and down his fields for eighty-six consecutive hours. He was wild with pain and mental distress. All remedies, both internal and external, seemed to have no effect whatever. Bleeding seemed to allay the itching, but as soon as the blood ceased flowing all the pain and itching returned. He was finally quieted by hypodermics of morphine every twelve hours until six doses had been given. After this the itching returned, in a moderate degree, and was alleviated considerably by local agents. This continued about four months, and finally subsided.

Iodoform Ointment in Tubercular Meningitis.

Dr. Martel, in the *Revue des Sciences Médicales*, calls attention to some cases of tubercular meningitis which were all cured by Dr. Warfwinge, a Swedish physician, by means of an ointment composed of iodoform

and vaseline (1 to 5). This was rubbed into the shaven scalp, twice a day, five grammes of the ointment being used each time, and a cap of some impermeable material worn constantly. The time required for cure varied, in the five cases in which this treatment was tried, from nine to thirty-two days. Dr. Martel remarks that the fact of five patients having been all cured is quite sufficient to recommend this method. "The future will tell us what it is really worth, and instead of remaining passive in presence of this disease, hitherto considered incurable, which has claimed such a multitude of victims, especially in Paris, it is the physician's imperative duty to make trial of every method of treatment which experiment, observation, and clinical experience places within his power." Though Dr. Martel speaks of this treatment as quite new, it was first proposed and employed by another Swedish physician, Dr. Emil Nilsson, who used an iodoform ointment of the strength of 1 to 10.

A Novel Treatment of Phthisis.

Dr. Bergeon, of Lyons, recommends a method of treating phthisis which has, at any rate, the merit of novelty. His plan is to utilize the effects of sulphuretted hydrogen, and this he proposes to do by injecting carbonic acid gas, saturated with sulphuretted hydrogen, into the intestines. If care be taken to secure the absence of atmospheric air, no inconvenience, it is said, results from the injection even of large quantities of the mixture; absorption into the venous system and elimination by the lungs taking place very rapidly. It is claimed for this procedure that, by its means, the use of sulphuretted hydrogen is unattended with any toxic effects, and exerts its influence directly on the lungs themselves. It has been employed in a number of cases at the hospitals of Lyons, Bordeaux, and Paris, with great benefit to the patients, even in very advanced cases, and, latterly, similar observations have been made in the consumption hospitals of London, the results of which have not yet been made known. The method has been very much simplified by the introduction of an ingenious but simple apparatus whereby the carbonic acid gas is generated, and saturated with sulphuretted hydrogen, ready for use.

Chronic Zona.

M. Leudet, of Rouen, read a communication at the Medical Congress at Nancy on chronic zona. He had met with it under three forms—(1) local chronic zona, (2) zona propagated from one nervous branch to another, (3) remote and successive zona. Zona was often secondary to peripheral, cerebral, or medullary lesion in the track of the nerves. The first case in which zona was observed was that of a child attacked by pulmonary tuberculosis, chiefly affecting the same side as that of the nerve-lesion. MM. Chaudeleit, Lesser, and Cadet-de-Gassicourt had collected notes of cases which demonstrated the influence exercised by chronic lesions of the pleura on the development of zona. A chronic form of zona had been remarked by M. Leudet in the case of two patients, the subjects of pulmonary tuberculosis, simultaneously with recrudescence of tuberculous growth. The cutaneous lesion provoked new ulcerations of the scars, sometimes accompanied by pseudo-phlegmon. This state might continue for three or even six months, at the same time inducing keloid. Recurrent zona in the same patient might occur in the same or other parts of the body.

Cocaine in the Treatment of Gonorrhœal Ophthalmia.

Mr. A. Leahy reports (in the *Indian Med. Gazette*, July, 1886,) two cases of gonorrhœal ophthalmia, in both of which the greatest benefit was derived from application of cocaine. As it is well known, in gonorrhœal ophthalmia, it is of primary importance to lessen the inflammation rapidly, to relieve the intense congestion of the conjunctival vessels and reduce chemosis, and by so doing prevent ulceration and sloughing of the cornea. Last, but not least, is the relief of the ocular and circum-orbital pain, which, by its persistence, greatly depresses the patient and prevents sleep. Mr. Leahy employed a mixture composed of one-half grain of sulphate of atropine and four grains of sulphate of cocaine incorporated with 100 grains of vaseline. This mixture was introduced beneath the upper eyelids; and after three days' treatment the chemosis rapidly became less, the discharge diminished in quantity, the pain completely disappeared, and the cornea, which had been hidden by the chemosis, became visible.

"Taking the Temperature."

Professor Filatow recommends a very convenient method of taking temperature observations, which consists in first warming the thermometer (for example, by rubbing it with a pocket-handkerchief or a corner of the bed-clothes) to about 110° Fahr.,

and then quickly inserting it under the patient's axilla. The mercury falls rapidly to the body-temperature of the patient, and after one minute, or a little more, remains stationary, at a point only a little below the real temperature of the body. Between 100° and 104° Fahr., the difference, according to Filatow, is only 0.18° Fahr.; for temperatures nearer normal, a little more, 0.36° to 0.54° Fahr. Much time is saved by this method. Dr. Biedert, of Hagenau, has carefully examined this procedure, and finds that six minutes' time should be given, as otherwise quite misleading results may be obtained (*Berliner Klin. Wochenschr.*, No. 43). With this proviso, which goes far to neutralize the chief advantage alleged in its favor, the method is stated to be reliable.

Gastric Syphilis and Simple Ulcer of the Stomach.

The *St. Louis M. and S. Jour.* says that L. Galliard some time ago published a paper in the *Archives dé Médecine*, whose conclusions are worthy of reproduction. He says that gastric syphilis does exist. In proof of this, we have a number of important clinical facts, anatomical facts that might be called into question, and also unquestionable anatomical facts, such as two ulcerated gummata of the stomach. Syphilis of the stomach is perhaps less rare than has been generally believed up to the present, leaving aside amyloid degeneration. By a close study of certain so-called simple ulcers in syphilitics either during their ulcerative process or after cicatrization, Dr. Galliard believes that we may be able to establish the pathogenetic rôle of syphilis in their production, or be able to describe more precisely the characteristics of the ulcerative syphilides of the stomach. The practical results of such observations would be the useful application of specific treatment in this variety of gastric disorders.

Eczema of the Eyelids.

Allen states (*Journal of Cutaneous and Venereal Diseases*) that eczema may attack the lids when other regions of the face, and possibly of the body, are at the time quite free. The treatment consists in applying to the closed lids a 3 per cent. solution of nitrate of silver, and drying immediately with a linen cloth, repeating the process several times at each sitting, all vesicles and pustules having been previously opened. The applications are made at first each day, and as improvement goes on every second day, after a few brushings there is scarcely any pain. An ointment composed of ol. cadini ʒj, pulv. zinci oxidi ʒiss, and vaseline ʒj, should be constantly applied in the intervals. If this ointment should prove irritating to the eyes, a mild white precipitate ointment may be substituted. Such constitutional remedies as are indicated may be employed in addition.

Stretching Sphincter Ani.

Before a recent meeting of an English medical society, Mr. J. W. Teale read notes of a case of a lady, aged 64, who, after prolonged and obstinate constipation, with albuminuria, was seized with left hemiplegia, accompanied by much convulsive movement of the affected side. In the prolonged unconsciousness which ensued, her sphincter ani was stretched, which was followed by copious action of the bowels. The patient made a fair recovery, and the albumen was reduced to a trace only.

Mr. T. P. Teale described cases of rigid sphincter ani without spasm, giving the sensation of a cartilaginous ring to the touch, and relieved by stretching.

Mr. Fletcher Little remarked on the less frequent occurrence of obstinate constipation among elderly women in France, where enemata were more largely used.

Reflex Epilepsy Caused by Larvæ of Insects.

A tanner, forty years old, was taken suddenly ill on June 14th, with anorexia, griping and mental oppression, and toward evening had a veritable epileptic seizure. A saline purgative administered to the patient caused the passage of several thousand larvæ, which Leuckart recognized as being those of the *musca vomitoria* and *anthomya canicularis*. Upon this discharge the attack was cut short. The case is an interesting one, says the *Deutsche Medezinische Wochenschrift*, from a double point of view, since it not only places beyond a doubt the possibility of symptomatic epilepsy due to entozoa, which was hitherto disputed, but it also demonstrates the danger of ingestion of cold meats, left where they can be reached by the flies in question. The ova are deposited on the meat, and, unlike the latter, are not affected by the destructive action of the gastric juices.

Pneumotomy.

M. Reclus recently described, to the Paris Surgical Society, a case which showed that the diagnosis of pulmonary hydatids was sometimes excessively difficult. A hydatid

cyst of the chest was diagnosed in a young girl; an exploratory puncture was made. The contents of the cyst were vomited by the patient, and it was believed that she had a pulmonary cyst. In order to open the sac more completely, M. Reclus performed resection of the twelfth rib. This operation showed that the patient was suffering from hepatic cyst. She was ultimately cured. M. Bouilly stated that M. Moutard Martin had performed thoracentesis on a patient who, it was believed, suffered from empyema, and he discovered that a hepatic hydatid tumor had opened into the bronchi; the sac was lined with pulmonary tissue.

Treatment of Housemaid's Knee.

With regard to the treatment of housemaid's knee, in the first two stages of the disease surgical writers usually advise, after tapping by means of a small trocar or aspirator, the employment of pressure by means of strapping. It has been the practice of Dr. Geo. Saunders (*Brit. Med. Jour.*) not to use strapping, but a piece of lead about the size and thickness of a crown piece, wrapped in lint, and placed over the patella, and then firmly and equally to bandage the knee, which should be continued for about a month. Previous to tapping, the part should be painted with iodine, and also occasionally afterwards. He does not consider it necessary to confine the patient to bed longer than two days. He has treated bursæ on the back of the wrist on the same plan with satisfactory results.

Gangrene Caused by Iodine Collodion.

The application of iodine collodion to a frost-bitten finger in Vienna last year, it will be remembered, led to a loss of the finger, and the suicide of the physician from mortification on account of the unfortunate notoriety given to the case. Dr. Vogelsang, of Biel, now reports (Memorabilia, *Med. Chir. Rundschau,*) a case in which iodine collodion painted over a large surface was followed by gangrene of the skin and sloughing. In one case collodion was applied over a gland which had been painted with iodine. The result was a slough and an ugly ulcer.

Hœmophilia.

In the *Brit. Med. Jour.*, November 27, Dr. Low relates a case of this disease. The patient was a young man, aged twenty-seven, who had had occasional epistaxis all his life. Within the last two years, the bleeding had occurred about once a fortnight, and had been very considerable. Nine relatives, seven males and two females, had suffered more or less from the same complaint. His grandfather died of apoplexy after the nose had been plugged for epistaxis, and his mother died of epistaxis.

Giving Quinine to Children.

In the *Miss. Valley Med. Mo.*, Dr. L. H. Davis says that in administering quinine to children much annoyance may be saved to both attendant and patient if the quinine be dissolved in good brandy and rubbed in as indicated. This is very reliable, and will produce cinchonism in almost as short a time as if administered per orem.

News and Miscellany.

The Means of Preventing the Deterioration of Rubber Apparatus.

An inquiry has been carried out under the direction of the French Minister of War with the object of ascertaining the cause and the remedy for the peculiar changes which articles made of India-rubber undergo when kept in stock, the annual loss to the government from the deterioration of this class of goods being very considerable. Experience shows that India-rubber, after a time, loses the very qualities which make it useful, for it becomes dry and brittle. Articles kept in boxes, such as Higginson's syringes, Esmarch's bandages and drainage tubes, are particularly liable to deterioriate, as are also the insufflation bulbs so largely used in connection with spray-producing apparatus and thermo-cauteries. Unfortunately, the results of a long and patient investigation are not by any means satisfactory, so far as the discovery of a means of prevention is concerned. Nevertheless, certain precautions are advised, both in the quality and storage of India-rubber goods, which, it is hoped, will do something to minimize the loss. The commissioners advise, for instance, that Esmarch's bandages should be taken out of the boxes at least once a month, unrolled, and manipulated. Drainage tubes should be hung up in a cool place, or soaked in a non-putrescible fluid. Finally, all objects made of rubber should be kept in a cool, damp place, at a constant temperature, and sheltered from light, heat, and frost. Seeing that, in many cases, these conditions cannot be complied with, it is recommended that the bandages should be made of pure leaf rub-

ber, in lieu of the elastic tissue usually employed. The purer the rubber the less readily does it undergo these structural alterations, and the lighter it weighs: its weight is therefore a sure guide to its quality. In consequence of these inquiries, the minister has ordered that in future all rubber articles are to be made with pure rubber of the best quality, preferably with the leaf rubber. The quality of the articles will be gauged by their specific gravity, in order to insure the purity of the material employed.

How a Citizen of Centre County Paid His Doctor's Bill.

The *Centre Hall* (Pa.) *Reyorter* says:

"Many of the old readers of the *Reporter* will remember Dr. Bigelow, a noted physician who practiced in the lower end of this valley some sixty years ago, when cheating had not been thought of or introduced as a Yankee invention. Dr. Bigelow's practice extended over half the valley, for he was a physician who understood his business and always minded his own business, which rendered him immensely popular. Among the families attended by him was the well known Heckman family, grandfather of the present Heckmans in our valley, and in whose noble breast there lurked no motive of dishonesty. Dr. Bigelow having made up his mind to leave Pennsylvania and locate elsewhere, he began to call upon those who owed him for settlement, as he had a habit of letting the honest old farmers have their own time about it. Coming to Father Heckman he told him he intended moving away, at which the old gentleman expressed his regret, adding that he hoped the doctor would make out his bill before moving so he could pay him. The doctor replied that his bill was seventy-five dollars. At this the old patriarch rose from the chair, seized his cane and went, not for the doctor, but upstairs, presently returned with a sack which contained about a peck of silver coin, and emptied the jinglers on the table with the remark: 'Now, doctor, whatever your bill is just take it out of that pile.' 'Oh, no,' said the doctor; 'I want you to count it out.' 'No, no,' said Heckman, 'you count it, doctor; you know best when you have enough.' The physician counted out his $75, when the farmer again insisted he should be sure he had enough. After a minute's change of conversation Grandfather Heckman again went at Bigelow with: 'Now, doctor, if you haven't got enough, go to the pile there and help yourself.'"

Humboldt and the Lunatic.

A story, says the *Boston Medical and Surgical Journal*, is told by a French paper of Baron von Humboldt, who, during one of his visits to Paris, expressed to his friend, Dr. Blanche, the distinguished authority on matters concerning insanity, a desire to meet one of his patients.

"Nothing easier," said Dr. Blanche. "Come and take dinner with me to-morrow."

Next day Humboldt found himself at the dinner-table of the famous alienist, in company with two unknown guests. One of them, who was dressed in black, with white cravat, gold-bowed spectacles, and who had a smooth face and very bald head, sat with great gravity through the entire dinner. He was evidently a gentleman of undoubted manners, but very taciturn. He bowed, ate, and said not a word.

The other guest, on the contrary, wore a great shock of hair brushed wildly into the air; his shabby blue coat was buttoned askew, his collar was rumpled, and the ends of his crazy necktie floated over his shoulders. He helped himself, ate, and chattered at the same time.

Story upon story did this incoherent person pile up. He mixed the past with the present, flew from Swedenborg to Fourier, from Cleopatra to Jenny Lind, from Archimedes to Lamartine, and talked politics and literature in the same breath.

At the dessert Humboldt leaned over and whispered in his host's ear, glancing at the same time at the fantastic personage, whose discourse was still running on.

"I am very much obliged to you. Your maniac has greatly amused me."

"My maniac!" said the doctor, starting back. "Why, that isn't the lunatic! It's the other one."

"What! The one who hasn't said a word?"

"Certainly."

"But who in the world can the man be who has talked in this fashion all the while?"

"That is Balzac, the famous novelist."

Jewish Burial.

Mr. Frederick W. Lowndes communicates to the *Lancet* a letter he has received from Mr. Barnard Levy, President of the Burial Board of the Liverpool New Hebrew Congregation, giving the following very interesting account of the simple and inexpensive manner in which the funerals of members of the Jewish persuasion are carried out:

"About two hours after death the body is

removed from the bed and carefully placed on the ground, with clean straw or shavings under it, and covered over with a clean sheet. It is then left for about thirty-six hours. On the expiration of that time the body (if its state permits) is washed by persons appointed for that purpose, who bring the necessary appliances. The shrouds, which cost for an adult about 17*s.*, are then placed on the body, which is then consigned to a common deal coffin (cost 16*s.*). At the time fixed for the funeral, the family and friends assemble. We have no scarves, plumes, or anything of the kind, and anything in the way of refreshments is unheard of. The cost of a hearse varies from 12*s.* 6*d.* to £1 1*s.*, and, as a rule, we employ very few black coaches. Personally, I do not approve of them, and I usually recommend the employment of cabs, at a cost of 5*s.* 6*d.* each. On arrival at the burial-ground. the coffin is carried on a hand-bier to the chapel, where the usual religious service is held, and thence to the grave, which is never bricked, and in which we never inter more than one body. The expenses, of course, vary with the number of coaches employed. In conclusion, I think I may say that the last services to the dead as conducted by my co-religionists are carried out in a reverential spirit, and will bear favorable comparison with those of any other sect."

Medicine in Zanzibar.

The *Deutsche Koloniazeitung* publishes a long communication from "Emily Ruets, Princess of Oman and Zanzibar," begging female European physicians to go out to Zanzibar. What the state of medicine is in the Arab houses may be imagined from an account which the lady gives of a favorite prescription in severe cases of illness. In moderate sickness, she says, decoctions of herbs are much used; but when a patient's case is serious, the believing Moslem prefers to resort to "swallowing texts from the Koran. A person noted for piety is called to indite the text with a solution of saffron on a white plate; the writing is then covered with rose-water, and given to the invalid to drink. This medicine must be swallowed thrice a day, and care must be taken that not a single drop of the sacred fluid is spilt upon the ground." The lady asks for physicians of her own sex because it is quite impossible for male doctors to exercise their art in the Arab harem. "No male physician," she writes, "would be permitted to feel the pulse, or even to inspect the tongue, of a female patient." Female physicians, on the contrary, would be readily welcomed, for the hearts of the Arab women are easily won to confidence. The ladies would not only do a good work, but they would find their offices well paid, and even profitable, from a business point of view. It would be necessary for them to learn a little of the Arabic and Suahelic languages in order to communicate freely with natives. "If a small society of duly qualified ladies will but venture out," she concludes, "I will engage only too gladly to give all the help I can towards their instruction in these tongues, in the consciousness that I should thereby be serving my beloved land."

How to Promote Temperance.

Cardinal Gibbons, of Baltimore (the head of the Roman Catholic Church in this country), in writing the preface of a little book for the guidance of a temperance confraternity just organized, expresses his views on prohibition legislation as a remedy for intemperance. The cardinal says:

"We approve of the confraternity, as it carries out the recommendations of the prelates of the last Plenary Council of Baltimore, entreating pastors in charge of parishes to establish temperance societies based on religion. There are three modes ordinarily proposed by advocates for the repression of intemperance. The first mode is by civil legislation, but this plan does not afford an adequate remedy, as experience abundantly demonstrates. Men can never be coerced or legislated into morality. The second is by appeal to popular enthusiasm and emotional religion. But this system is equally inefficient, whatever may be the good intentions and zeal of its advocates, for as soon as the excitement subsides the disease resumes its sway, and moral distempers are too deep-rooted to be eradicated by an enthusiastic harangue or by any appeal to the feelings. The third and only effectual method, in our judgment, by which intemperance can be repressed is by religious and moral influences, which not only appeal to the intellect and the heart, but which impart grace to effect what unaided nature is unable of itself to accomplish."

Can Imagination Kill?

A young woman in Hackney, England, recently took Keating's insect powder with suicidal intent, and actually died. Dr. Tidy, an expert chemist, was employed to show what the ingredients were which pro-

duced death. He reports the powder perfectly harmless, and that the deceased came to her death from her imagination that the powder was a virulent poison.

This brings to our mind, says the *Lancet*, two remarkable instances of what may be regarded as practical jokes with melancholy terminations. A convict was delivered up to the scientist for the purpose of a psychological experiment. The man was strapped to a table and blindfolded, ostensibly to be bled to death; a siphon containing water was placed near his head, and the fluid was allowed to trickle audibly into a vessel below it, at the same time a trifling scratch with a needle was inflicted on the culprit's neck; it is said that death occurred at the end of six minutes. The case of a college porter is also one in point. The students entrapped him into a room at night a mock inquiry was held, and the punishment of death by decapitation was decreed for his want of consideration to the students. The supposed earnestness of his tormentors, the sight of an ax and block, with subsequent blindfolding and necessary genuflexion, a smart rap with a wet towel on the back of his neck was followed by the picking up of a corpse.

The Intelligent Irregular.

The *Cincinnati Lancet and Clinic* says that upon a certain occasion Mr. Williams (afterward United States Judge for the Territory of Iowa) was defending a client in the interior of Pennsylvania against the claim of a quack doctor (who professed everything and knew nothing), and who had instituted a suit for surgical services, and had marked the suit to the use of another in order to become a witness. The following was developed during the cross-examination:

Counsel—"Did you treat the patient according to the most approved principles of surgery?"

Witness—"By all means—certainly I did."

Counsel—"Did you decapitate him?"

Witness—"Undoubtedly I did; that was a matter of course."

Counsel—"Did you perform the Cæsarian operation upon him?"

Witness—'Why of course; his condition required it, and it was attended with great success."

Counsel—"Did you now, doctor, subject his person to an autopsy?"

Witness—"Certainly; that was the last remedy adopted."

Counsel—"Well, then, doctor, as you performed a post-mortem operation upon the defendant, and he survived it, I have no more to ask, and if your claim will survive it, quackery deserves to be immortal."

The Food of Paris.

The following returns, taken from the Prêfet's annual report of the quantities and description of food consumed in Paris last year, may be regarded as fairly reliable: Meat figures at 149,495,306 kilogrammes (146,825 tons), which is an increase of 445,952 kilogrammes on 1884. There has been a diminution in the consumption of pork to the extent of 147,389 kilogrammes, but there has been a great augmentation in the consumption of horseflesh, which is rising every year. The total quantity of this delicate viand eaten last year was 3,831,206 kilogrammes, and the increase on the year was 337,926 kilogrammes. The figures for the amount which was palmed off for something else are not available. The average price was 60 centimes per kilogramme for the horse, and 70 centimes for asses and mules, which is about 3d. and 4d. a pound respectively. The total of poultry and game was 25,044,149 kilogrammes, a diminution of 565,849 kilogrammes. Of fish, 25,631,404 kilogrammes were eaten. This increase was in part due to the large quantity of oysters eaten. The consumption of butter and eggs had fallen by 160,337 kilogrammes. Butter had been to a great extent replaced by fats and margarines.

Preventive Inoculations for Hydrophobia.

The *Boston M. and S. Jour.* tells us that Dr. Valentine Mott, of New York, has been making a series of preventive inoculations in the case of two sons and an office-boy of Dr. T. W. Foster, of Yazoo county, Miss., who was bitten by a rabid dog on the 3d of November. Immediately afterwards Dr. Foster left home with the intention of taking the boys to Paris to be treated by Pasteur; but learning, on his arrival in New York, that Dr. Mott was provided with proper material for inoculating, which had originally been obtained from Pasteur, he decided to have the treatment carried out here. The process has now been completed, and the children, who suffered no inconvenience from the inoculations, are all in good condition. The young son of Dr. Nowell, of Jersey City, who was bitten by a dog supposed to be rabid, in June last, and afterwards subjected to the Pasteur treatment at the hands of Dr. Mott, continues well up to the present time. In his case the inoculations were

discontinued after four had been made, as the boy exhibited certain distressing cardiac and respiratory symptoms for a short time after each inoculation, and his father was unwilling to have the treatment continued any longer.

Mark Twain on Columbus' Discovery.

Mark Twain, the humorist, was recently asked to introduce Henry M. Stanley, the great African explorer, and this is how he did it:

"I am not here to disparage Columbus. Now Columbus started out to discover America. Well, he didn't need to do anything at all but to sit in the cabin of his ship and hold his grip and sail straight on and America would discover itself. Here it was barring his passage the whole length and breadth of the South American continent, and he couldn't get by it. He'd got to discover it; he couldn't help it. Neither did he have to find any particular part of America, and when he found any portion of it his contract was fulfilled. But Mr. Stanley started out to find Dr. Livingstone, who was hidden away somewhere, scattered abroad, as you may say, over the length and breadth of a vast slab of Africa as big as the United States. It was a blind kind of search. He was the worst scattered man. He was the scarcest commodity there was; he was as scarce as a teetotaler in a prohibition State. Now, it wouldn't do to send me out to hunt for a man. I shouldn't find him; he wouldn't be there when I got there."

Centenarians.

The *Brit. Med. Jour.* says that centenarianism is certainly more prevalent than formerly, if we are to believe the newspaper reports. Mrs. Ann Lanchester, of Hunton, Yorkshire, is at present enjoying good health in the 105th year of her age, having been born at Galley Hill, near Bowes, on Royal Oak Day, 1782. She has quite recently been haymaking, and teaching some of her great grandchildren to use the sickle. There is now residing in the parish of Wender, near Saffron Walden, Essex, an old gentleman named Richard Nicholson, who has turned his 103d year. He is hale and hearty, and in full possession of all his faculties. And within the last few days the death of the widow of a staymaker at Christopher Buildings, Marylebone, was reported, at the age of 106; of that of Stephen Phipps, in Staines Union Workhouse, at the age of 101; and of that of the widow of a lighter-man, in Queen Street, Southwark, at the age of 100.

He Liked the Taste.

The *Toledo Blade* is responsible for the following:

Drug Clerk (to customer) — "Twenty grains of quinine? Yes, sir. Shall I give you something to take away the taste of it?"

Customer (eyes bulging with astonishment)---"Take away what?"

Drug Clerk—"The taste of the quinine, sir."

Customer (solemnly): "Young man, quinine is bread, butter, an' pie to me. It's parients, relatives, fren's; it's my washin', ironin', clothin', and a place to sleep in. Take—away— the— taste—of —it! I'm a Wabash Valley man, and I'm a good mind ter comb ye down."

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDED DECEMBER 18, 1886.

Banks, C. E., passed assistant surgeon. Granted leave of absence for twelve days, December 16, 1886,

Carrington, P. M., assistant surgeon. Granted leave of absence for fifteen days, December 6, 1886.

Williams, L. L., assistant surgeon. Upon expiration of leave, to proceed to Boston, Mass., for duty, December 17, 1886.

Diminutive Mail Matter.

The postal service at Liverpool, England, recently had an experience which, if often repeated, will prove the reverse of amusing. Some one whose ingenuity or economy was searching for new fields, wrote a message of twenty-six words on the back of a two-cent stamp, which was duly posted and delivered. This success led to a second experiment, and then to a third. But, on the last occasion, a 1-cent stamp was chosen, and was accordingly held as an insufficiently prepaid letter.

Awfully Embarrassing.

They had joined the ladies after dinner, and the conversation had turned to matters dramatic, and thence to disturbances during a performance. "Do you know," said the hostess, "I think children at the theatre are a nuisance. I was at Wallack's the other night, and a woman had a baby in the parquette—." Just then the sleepy one in the corner woke up and exclaimed: "Dear me, how awfully embarrassing; but I suppose there was a doctor there?"

A Wooden-Legged Cow.

Some eighteen months ago Mr. John Sharry, V. S., of Norton Malton, England, successfully amputated one of the hind legs for injury, of a valuable and well-bred short-horn cow, the object being to retain the cow for breeding purposes, while a wooden leg was affixed to the stump. Many will be pleased to hear that the object has been fully achieved; the cow is a mother, and has a fine bull calf running by her side.

Please Wipe Your Feet.

The janitor of a very dirty lodging-house had posted up at the entrance the usual notice:

"Visitors will please wipe their feet."

A practical joker, after having inspected the apartments one day, added the following:

"On going out!"

Items.

—A Boston lecturer says "women will never be healthy until they dress after the Greek fashion." Even then they might have peri-chiton-itis!

—That present of a copy of Dante's "Inferno" from the King of Italy to President Cleveland was timely and appropriate. The volume may enable Mr. Cleveland to discover the original sources of pernicious rheumatism.

—The Cincinnati *Lancet-Clinic* says that the Noble County (Ind.) Medical Society receives $500 a year for all the sick paupers in the county. The member nearest the pauper treats the same. The money is used for building up a society library.

—It is estimated that nearly 200 cures for rheumatism have been sent to Mr. Cleveland since he was taken with that distressing ailment. The worst of the whole business is that it is is proposed to try them all on Col. Lamont to see if any of them are effective.

—A saloon-keeper at West Side, Iowa, placed on his bar a whisky bottle filled with liquid ammonia. An agent of temperance came along presently, drew out the cork of the suspicious-looking bottle, and took a hearty sniff of its contents. A crowd of loungers laughed loudly over the result.

—Professor Zweibeer is a very absent-minded man. He was busily engaged in solving some scientific problem. The servant hastily opened the door of his studio and announced a great family event: "A little stranger has arrived." "Eh?" "It is a little boy." "Little boy! Well, ask him what he wants."

—In a police court:

Complainant—"Yes, your Honor, I recognize this handkerchief. It is mine."

Magistrate—"What makes you think so? I don't see any mark on it, and I have one just like it in my pocket."

Complainant—"Possibly, your Honor; I have lost several."

—It cost a fashionable lady who was sojourning at Saratoga last summer $300 for doctors' bills for attendance on a pet dog which was taken sick. She thought the charges very reasonable, but complained when the nurse informed her that her little daughter had a severe cold and she had paid twenty-five cents for a bottle of cough medicine. "Children are awful expensive things," she said, "and I don't know why they have to get sick."

—Talking about busy men who leave their homes early and get back after dark and never see their children, a man of that sort was hurrying away one morning when he found that his little boy had got up before him, and was playing on the sidewalk. He told the child to go in. Child wouldn't. Man spanked him and went to his business. Child went in howling. The mother said: "What's the matter?" "Man hit me," blubbered the youngster. "What man?" "That man that stays here on Sundays."

OBITUARY NOTICE.

BENJAMIN F. ROSS, M. D.,

Died in Cobden, Ill., at his residence, December 15, 1886.

Dr. Ross was born in Franklin county, Pa., in 1832; came to Illinois while quite young; studied medicine with Dr. Phipps, of Nashville, Ill., and graduated from Rush Medical College, Chicago, in the class of 1858. He located in Cobden, on the Illinois Central Railroad, in April, 1858, when there were but a few houses in the town, where he continued in active practice up to the time of his death.

Dr. Ross was a charter member of the Southern Illinois Medical Association, and was highly regarded by all physicians who knew him. His death is very much regretted in the community in which he lived, and was the result of chronic unresolved pneumonia, induced by exposure three years ago.

DEATH.

WELFLEY.—Dr. D. P. Welfley, one of the leading physicians of Cumberland, Md., died December 21, of typhoid fever.

Pallas Syringe."

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten acres. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

THE PHYSICIAN'S
DAILY POCKET RECORD AND VISITING LIST.
By S. W. BUTLER, M. D. TWENTY-FIRST YEAR.

A New Revised Edition for 1887, with Metric Posological Table, &c., strongly bound in Dark Morocco, with Pocket for Blanks, and a Patent Steel Spring.

THIS VISITING LIST has been a favorite for many years. It is "perpetual" in arrangement, and may be used continuously one full year from the date of the first entry. Besides the Posological Table, it contains Tables of Doses for Hypodermic Injections, Inhalation, Suppositories, &c.; Directions for the treatment of Poisoning, Drowning, and other emergencies; Simple Directions for Testing the Urine; Obstetric Record, Cash Record, &c.
☞ This RECORD has met with the Highest Praise from those who have made use of it.

PRICES.

Editions for Thirty Patients Daily, Patent Clasp, ... *$1.50*
Editions for Sixty Patients Daily, Patent Clasp, ... *$2.00*

☞ **The Name of the Purchaser will be Stamped in Gilt Letters, on the Back, for Ten Cents Extra.**

A reduction of 50 cents on these prices will be made to subscribers to THE MEDICAL AND SURGICAL REPORTER and QUARTERLY COMPENDIUM when taken together.

OIL OF TURPENTINE IN CHRONIC CATARRHAL AFFECTIONS.*

BY JAMES B. WALKER, M. D., PH. D.,

Professor of Principles and Practice of Medicine in Woman's Medical College of Pennsylvania, One of Visiting Physicians to Philadelphia Hospital, etc.

What I may say on the subject of terebinthinates can present no claim for originality, for "Pliny describes several varieties of turpentine, and speaks of their use for coughs and ulcerated bowels." (Stille's Therapeutics"), and "Boerhave and others in the last century recommended the oil for chronic affections of the lungs and bowels." (Ibid.) John Hunter advises it in hemorrhages, stating: "I have seen it immediately stop vomiting of blood from the stomach after all other means had failed;" adding, "it is the best if not the only true styptic." In 1826, Dr. George B. Wood drew attention to its use in certain conditions of fevers marked with dryness of the tongue, tenderness, and slight distension of the abdomen, a frequent and feeble pulse, wandering intellect, and an anxious expression of countenance, which his own subsequent experience and that of numbers of others have abundantly verified. Stillé, in commenting upon this, states: ', Its mode of action appears to be, locally, that of a healthy excitant of the intestinal ulcers, promoting their cure; and at the same time that of a genial stimulant of the whole economy." Chapman, in his therapeutics, refers to its use in certain intestinal fluxes, and asserts that in chronic diarrhœa, where the discharges are such as to denote the mucous coat of the intestines to be chiefly affected, it is an incomparable remedy." But in spite of these historical facts, it is no less true that our text-books of to-day give but slighting testimony to its efficacy, and many of them ignore its usefulness in catarrhal conditions.

Turpentine taken internally is capable of impressing almost the entire mucous surface of the body. The exceptions are the uterus and vagina. It directly impresses that of the entire gastro-intestinal tract before absorption, and being eliminated by the renal and pulmonary tissues, reaches the mucous surfaces of the tracts communicating therewith. Such an agent, possessing decided powers of impressing tissues with which it comes in contact, must possess marked therapeutic value. Add to this its known powers as a *general stimulant* through the blood to the various tissues with which it is brought in contact, during its transit from entrance to exit, and we have its field of usefulness infinitely extended.

It is not my purpose, on this occasion, to call our attention to *all* it is capable of doing, but to limit the observations to its usefulness in the chronic catarrhal affections of the alimentary tract and the lungs. In hemorrhages from these surfaces it possesses peculiar powers. This is especially true of the stomach, in ulcers of whose mucous coat it stands pre-eminent. Here it can be brought in contact with the diseased and bleeding surface most directly, and in concentrated form. In hemorrhage of the intestines it is only a little less valuable, and even here it ranks with any other styptic, and outranks most of them. This is as true of the hemorrhages of the engorged mucous membrane in

*Read before the Philadelphia Clinical Society.

the earlier days of typhoid fever as of the hemorrhages from the ulcers at a later period. In the latter instance aids, such as opium, are indispensable, of course; but the direct styptic action of turpentine is unquestionable. But these are matters of everyday experience.

In the subacute and chronic diarrhœas, which are more or less prevalent in our variable climate, the remedy is used to a much less extent than its efficacy deserves. During the past few years my confidence in its value has been abundantly and increasingly stimulated in a somewhat extended experience in hospital and private work. I will cite an instance, as illustration, of a young woman who for several months had been tormented with a diarrhœa which persisted in spite of bismuth, opium, nitrate of silver, sulphate of copper, the mineral acids, and other well known agents, used singly or some of them combined, together with abstemious attention to a suitable diet. The diarrhœa would sometimes be checked, only to return with the cessation of the remedy. Oil of turpentine induced almost immediate relief, which was permanent. The diarrhœa, in this case, was of the nature of a "lientery." This is but one of a large number of similar experiences which I could detail more or less fully, did time permit, so that I have come to look upon the remedy as an incomparable one in cases of chronic diarrhœa where the mucous membrane over an extended tract is involved, in chronic inflammation.

In these cases bismuth is not so serviceable as in acute disease. Indeed, I reckon the value of bismuth in catarrhal diseases of the intestinal tract as great in the *acute* stages. but rapidly growing less in the *subacute* and *chronic* cases, its value being in inverse proportion to the chronicity; and in real chronic cases its mechanical presence, instead of being an *aid* to *reparative changes* seems to aid in keeping up the *irritation*. Opium in these cases, by lessening peristalsis, will arrest the diarrhœa, only to be followed on its cessation with an aggravation of the trouble. Lead and silver salts unquestionably serve to arrest the catarrhal conditions, and tend to repair the tissue; but how little their influence must be in the small quantities which can be safely administered, and the extensive surface upon which they must distribute their influence to be of any avail. Besides, in most of these cases the diseased areas are more or less protected from the influence of such agents as these by a tenacious environment of mucus. Here, it is true, the mineral acids have proven of inestimable value. But even when they have failed, as in the above instance, the turpentine has, in my hands, acted promptly and efficiently. The quantity taken in these cases can be considerable without fear of irritation, and the volatile nature of the agent enables it lo diffuse itself throughout the bowel, into all the interstices thereof, and to permeate even the mucous environment of the diseased glands, and directly impress these structures.

The best time for its administration in these cases is between meals and at bed-time. If, however, taken on an empty stomach its regurgitation is decided, it should be administered about an hour after a meal.

Another class of affections, equally favorably influenced by turpentine, is that associated with chronic bronchitis. Ammonia salts, from their influence on the respiratory act and on the respiratory tract have, in a great degree, crowded the terebinthinates to the wall. This is not as it should be. Both classes have their value; both have great value, but each has its own peculiar value. In proportion to the chronicity of bronchial catarrh, ammonia becomes of *less*, and turpentine of *more* value. This is simply the conclusion to which my experience has brought me. It may not agree with that of others; it may not be correct; but it seems to me to be justified by my own experience.

One of the earliest experiences I had with turpentine, in this class of cases, was in the case of a young man of slight build, about 21, who, during the exhausting latter days of an attack of typhoid fever, in which there had been more than the ordinary slight bronchitis with which almost all cases are characterized, developed a disseminated catarrh which involved the alveoli of one of the lungs, and developed numerous foci of catarrhal pneumonia. I had been watching the case for some time, as a consultant, and on the development of this condition advised the use of turpentine as the most desirable stimulant. One of our most eminent authorities was called to our aid after a few days, who verified the diagnosis, gave a very unfavorable prognosis, and sanctioned the use of the turpentine. Under its use convalescence was established, the lung entirely cleared, and the patient still remains well, and has since taken out a life insurance policy, after a rigid examination. Since then I have used this drug with increasing confidence, not only in catarrhal conditions, secondary to acute disease, but in primary catarrhal diseases, which linger and threaten

to involve the alveoli, or which have already involved the alveoli, and become entitled to classification as incipient phthisis. In the dry forms the drug has not seemed desirable, but in the form characterized with decided, or abundant expectoration its best effects are obtained. It is, of course, not a panacea. Many of these cases, despite its administration, go on from bad to worse, but in enough of them are beneficial results obtained to make me value the remedy as among the best.

Two other instances in which I have used the drug are as follows:

Case 1. Mrs. G., aged thirty-four, had a good constitution with no phthisical tendency. Early last winter she developed a bronchial catarrh, which she allowed to run on for six weeks withot giving it any attention. Upon examination, I found diminished respiratory power over the entire right side; fine moist râles throughout, most marked in the axillary and infra-axillary regions; limited pleuritic friction sounds in infra-axillary region; prolonged expiration, especially at the apex, and impaired resonance. Flesh and strength were rapidly lost, and the case threatened to be one of rapid phthisis; there were frequent chills, afternoon fever, and decided night-sweats. The main stimulant was turpentine, in pearls, ♏v. after each meal and at bed-time. This remedy would be kept up for three or four weeks, then discontinued for a week, giving muriate or carbonate of ammonium instead. As the cough was worse on lying down, inhalations of chloroform were used to insure sleep. By the time summer commenced, the patient's condition was much improved. There is remaining a slight crepitus over the pleuritic spot, but the lung is now as clear as it ever was, and the patient has regained her normal flesh and strength.

Case 2. Was a clerk in the office of the Pennsylvania railroad. One evening he had some spitting of blood, and on examination I found a pneumonic condition of the upper lobe of the right lung; there was not much solidification, but the respiratory force was much impaired. The patient was sent to the country for three months, during which time the lung cleared up nicely, turpentine being the one remedy.

Its method of administration may be varied. It may be given as terebene, oil of turpentine, or tar dropped into a pitcher of boiling water, and the vapors inhaled through a paper funnel—a method which is of advantage in the cases where the larynx and trachea are chiefly affected. Here, also, one of the many forms of oro-nasal inhalers may be used for the administration of terebene, oil of turpentine, etc. But where the smaller bronchi are invaded, inhalations are of doubtful local service, little, if any, of the remedy reaching the part. The internal administration is here indicated. The oil may be given in capsule, gelatine capsules being prepared by the dispensing druggist; or the more elegant French pearls may be substituted, containing ten or five drops of the remedy, and one or two of these given an hour after eating. In this form the drug is not tasted, unless regurgitated, and if taken an hour after meals will be so quickly passed into the intestine as to interfere but little, if at all, with gastric digestion. In intestinal catarrh it may be administered in capsule also, or if the patient is unable to swallow the pearls or capsules, an emulsion may be made, and the acrimonious taste of the turpentine may be entirely concealed by adding a small quantity of oil of anise seed, whose influence is adjuvant to the turpentine in the diseased conditions. In bronchial catarrh, where the ammonia salt seems also desirable, a combination like this may be used with advantage, and is quite a favorite of mine in cutting off harassing bronchial catarrhs, which persist in remaining:

℞. Ammon. chloridi, ℥iss.
Vini picis liquid., ℥ss.
Syr. tolutani, f℥j.
Aquæ, f℥ijss.
M. Sig.—Dessertspoonful every four hours.

But when catarrh involves the alveoli, I much prefer the turpentine itself.

If I have seemed to make too much out of a very small matter, I hope to be excused. My desire was two-fold: first, to call attention to a valuable aid in combating forms of disease only too prevalent in our climate; and secondly, to have my experience confirmed, or corrected, by that of my fellows. On the value of the drug in certain catarrhal affections of the genito-urinary organs, I prefer to be silent at present, both for want of time and of sufficient experience to be of much value.

SOME RECENT STUDIES AND OBSERVATIONS ON TINNITUS AURIUM.

BY LAURENCE TURNBULL, M. D., PH. G.,
Aural Surgeon Jefferson Medical College Hospital, Phila.

(*Continued from page* 6.)

In our public clinic there are numerous cases of tinnitus relieved and even permanently cured, as may be seen by our reports.

A few only require a simple examination of the ear, throat, and nose, to find out the cause. We would also state that there are a a very large number of cases of chronic disease of the middle ear, chronic catarrh, with constant and persistent noises as the chief symptom, which from organic changes long neglected, or improper treatment, cannot be cured by any means at our disposal.

We have noticed *under various causes* that "tinnitus aurium" results from affections of the middle ear, both in the anterior and posterior surface of the membrana tympani, cavity of the tympanum, and eustachian tubes. The noises in the internal ear have also been confounded with symptoms of an affection of the brain itself or its coverings. It is possible to have ringing noises in the ear even when there is, so far as our examinations can penetrate, no organic change in any portion of it.

In the post-mortem examinations of persons who have suffered from tinnitus for a long period without any known disease of the ear, Méniere, Politzer, Schwartze, and Hinton, on dissections of the petrous bone have found diseases of the semi-circular canals, ecchymoses in the vestibule, hyperæmia of the cochlea, general enlargement and fulness of vessels of the labyrinth.

We must, therefore, for the present, come to the conclusion that the semi-circular canals and vestibule are one of the chief seats of the diseased conditions above described, with now and then apoplectic or endo-labyrinthic disease with effusion in the labyrinth, showing more or less pressure within its walls or irritation of the auditory nerve. And second, to the various forms of disease of the ear enumerated in the first part of this paper under the third class of causes.

TREATMENT.

To the first class of cases to which we referred, namely, pressure from cerumen upon the membrana tympani, the treatment in the great majority of cases is simply to remove the offending cause by means of the injection of tepid water or weak solution of soda. Numerous cases, many of which are of a most distressing character, of this class are relieved by this simple procedure.

The excessive growth of stiff hairs in the meatus. The treatment consists in carefully cutting the hairs close up to their point of exit by means of curved scissors, and removing each one when cut. The objection to plucking them out is that it will frequently cause an abscess at the termination of the hair follicle. Another form of this same variety is when a hair becomes detached and falls upon the membrana tympani, from which it must be removed by means of a camel's hair pencil slightly moistened in glycerine.

Adhesive mucus on the posterior surface of the membrana tympani, in the middle ear or mastoid cells. This is removed by the use of the catheter or a few blasts from Politzer's air-bag or douche; if these means are not effectual, paracentesis of the membrana tympani and washing out the middle ear with a weak solution of biborate or sulpho-carbolate of soda in warm water. At the same time attention must be given to the naso-pharyngeal region, with the use of nasal sprays and gargles.

In *foreign bodies in the eustachian tube.* the treatment will be to reverse the action of the air-bag and withdraw the air, or by means of an elastic catheter in the pharyngeal orifice of the tube; compress the nostrils, and at the same time, by means of a valved bag attached to a curved glass tube introduced through the mouth as near as possible to the orifice of the tube, rarefy the air. Should the foreign body produce inflammation with effusion, bulging of the membrane, etc., its escape should be facilitated by perforation of the membrane by an aspirator needle.

The form *pulsating tinnitus,* is the result of some alteration in the blood-vessels, anæmia, or excessive action of the heart; we must try compression of the temporal or carotid, diminishing the frequency of the heart's action by aconite or digitalis, or if the patient is anæmic, administer the salts of manganese, or lactate or citrate of iron, avoiding all forms of excitement, as dancing, violent exercise, or mental effort.

We must make careful diagnoses by, exclusion, to discover whether we have excitement of the brain causing subjective noises, or on the other hand exhaustion from over effort or some drain upon the nervous system. In the first instance we resort to bromide of potassium or sodium, or if there is any suspicion of syphilitic complication, add bichloride of mercury and the iodide of potassium, with the active principle of jaborandi to produce great activity of the salivary and sweat-glands.*

If it is the latter, *i. e.*, exhaustion, we resort to a solution of phosphoric acid employed in the form of lemonade, or to the

*See mode of treatment by this agent and full account of case, Author's Manual of Diseases of the Ear. Third edition, just issued. J. B. Lippincott & Co., Philadelphia, 1887.

phosphites or hypo-phosphites, in conjunction with strychnia or its salts, with the use of the galvanic current to assist in completing the cure.

(*To be continued.*)

THE ELECTRO-DIAGNOSIS OF NEURITIS AND ANTERIOR POLIOMYELITIS.*

BY JAMES HENDRIE LLOYD, M. D.,

Instructor in Electro-Therapeutics in the University of Pennsylvania.

The irritability of a nerve-trunk to an electric current (either by galvanism or faradism) depends upon the integrity of the axis-cylinder. This integrity may be impaired by pressure upon or by a fracture of the axis-cylinder. The pathology of degeneration in a nerve-fibre is, first, an increase of protoplasm about the nucleus in the sheath, then the splitting up of the white matter, and, finally, the breaking of the axis-cylinder.† In neuritis it may be a question how soon this *fracture* takes place, but *pressure* evidently occurs very early, and in severe acute neuritis (as in some forms of facial paralysis) this pressure is very great, is very quickly established, and, in the worse forms, no doubt leads to the breaking of the axis-cylinder. If electro-irritablity, therefore, be retained in the nerve in neuritis, it must be either because the pressure is very slight, or else because of an escape of some nerve-fibres amidst the destruction of others. The first event is what happens in mild subacute neuritis, but the latter alternative does not seem very probable when the disease is interstitial in the narrow calibre of a nerve-trunk, and especially when it has continued a long while. On the other hand, in anterior poliomyelitis of slow progress, the large cells may be gradually and successively destroyed, followed by the degeneration of a comparatively few nerve-fibres—and in these cases the nerve will retain its electro-irritability (possibly diminished sometimes), although the muscles may have commenced to put on the modal and serial changes of degeneration. These facts have been long recognized, but do not appear of late to have been sufficiently relied upon as a possible factor in diagnosis.

De Watteville has drawn a distinction between myotrophic and neurotrophic centres in the cord; but the distinction, as well as his illustration, is artificial, and the phenomena probably depend upon the extent of degeneration and the number of nerve-fibres involved. His own opinion inclines to the view that where nerve-irritability (especially faradic) is preserved, especially in cases otherwise chronic, with muscular atrophy and muscular reactions of degeneration, we have a condition rather of atrophy of the anterior horns than of the nerve-trunks, affording strong corroborative evidence in establishing the differential diagnosis. It is this condition of retained nerve-irritability, with degeneration reactions to galvanism in the muscle, which we have in such slow cord-lesions as amytrophic lateral sclerosis and chronic anterior poliomyelitis. Here other symptoms aid the diagnosis, especially the large fibrillary contractions in the muscular atrophy and the spastic symptoms in lateral sclerosis. The only forms of neuritis that he knew of—in which faradic irritability of the nerve is preserved, with muscular reactions of degeneration—are essentially mild, non-chronic attacks (such as mild facial palsy), and in these the lesion is probably light compression, leaving the axis-cylinder unbroken.

It must be recalled that muscle-tissue alone will not respond to such strength of faradism as we use upon it in the clinic, but is excited through the motor-nerve-endings in its tissue; consequently when we have response in a muscle to faradism we infer that the nerve is still intact, or partially so. Hence, in severe facial palsy, one of the first symptoms is loss of farado-contractility.

Illustrative cases have been noted as follows:

1. A very marked case of chronic anterior poliomyelitis, in which both legs and arms were involved, with very great fibrillary contractions. Very exact notes of this case have been preserved, and show that while the affected muscles showed the slow, lazy contraction of degeneration, with slight changes in the normal formula, yet the nerve-trunks remained normal (or only slightly decreased) to faradism. This is just the condition which would be expected in anterior poliomyelitis, but we would not expect it in neuritis.

2. In this case there was a rapid wasting of certain isolated groups of muscles—as deltoid, infra-spinatus, and supra-spinatus (possibly biceps and supinator longus)—and with muscular reactions of degeneration there was rapid loss of nerve-irritability to faradism. This loss of farado-irritability, with absence of fibrillary contractions, also the circumscribed group of muscles in which it occurred,

---

* Read before the Phiiadelphia Neurological Society.

† Rauvin, as quoted by Gowers in "Diseases of the Nervous System," Part II.

was rather suggestive of a neuritis, destroying first the nerve-trunk.

3. A case of rapid and complete wasting of the muscles especially presided over by the nerves which are stimulated at Erb's motor-point; deltoid, spinati, biceps, and supinator longus. Nerve-irritability to both currents abolished; reactions of degeneration in muscles followed by loss of muscular irritability (except slight modal response); no fibrillary contractions; history of traumatism. All the symptoms as well as the history point to a neuritis of a few nerve-trunks in the plexus, and the electric examination confirmed this.

3. A marked case of facial paralysis with secondary contractions, with *total* abolition of nerve irritability to both currents and reactions of degeneration in muscle. This is a typical picture of a neuritis.

5. A case of amyotrophic lateral sclerosis (descending degeneration?) with spastic muscles, wasting and exaggerated reflexes. The nerves respond normally to both currents (showing certainly not a neuritis), while there are slight reactions of degeneration in the muscle. Cases somewhat like this have been reported by Hughes-Bennett.*

Conclusions.—The point sought to be emphasized is the retention of electro-excitability in the nerves, which in chronic cases does not appear consistent with the idea of a neuritis, but, rather, of a slow cord-lesion. If this electric excitability can be preserved in a chronic neuritis, we must suppose a very slow interstitial inflammatory process which compresses some fibres and allows others to escape. But to think that this happens in the narrow calibre of the nerve-trunk during a prolonged period of inflammation seems to require some effort of imagination and credulity. The electrical reactions in the above cases (especially the condition of *nerve*-irritability) support the other symptom-groups in their significance as to a cord or a nerve lesion.

Walnut and Fortieth strects.

MORBUS CERULUS FROM A MALFORMED HEART.

BY E. S. M'KEE, M. D.,

Of Cincinnati, Ohio.

April 22, 1881, while on duty in the outpatient obstetrical department of St. Bartholomew's Hospital, London, England, I was called to attend a woman in labor. The delivery was without note, but the child showed marked evidences of cyanosis. This disappeared on the second day. On the third day a messenger called me in haste, saying, "the baby is queer, has convulsions, and don't notice anything." The convulsions, of course, were over before I could get there. The child then had the thrush, from which it recovered, but seemed to suffer from an ill-defined trouble. On the fourteenth day it lay perfectly still, most of the time on its right side. The cyanosis reappeared, especially in its fingers, toes, and lips. Died on the fifteenth day. Autopsy fourteen hours after death. Head somewhat enlarged, calvarium and meninges healthy. Both lateral ventricles were filled anteriorly with clear serum, posteriorly with puriform and softened brain matter. Each ventricle was distended one-fourth of an inch; third ventricle also distended, but the iter a tertia ad quartum ventriculum and fourth ventricles nearly normal. Choroid plexus and other parts nearly normal. On the under surface of the brain the pia mater covering the pons, cerebellum and medulla was covered with flakes of lymph. No sign of tubercle could be found. Lungs normal.

Heart.—No excess of fluid in the pericardium. Organ of normal size, but on examination the right auricle was found a little enlarged, and the left auricle small internally, but admitting the pulmonary veins. Internally the valves were all normal. The septum between the ventricles was incompiete in its upper part and led into a common artery representing the aorta, closed by three normal semi-lunar valves. The orifices of the two coronary arteries lay behind the two anterior valves. Both ventricles normal. Foramen ovale normal but closing. The remains of the pulmonary arteries consisted in an upward prolongation from the right ventricle, and a tube which opened above into the aorta was separated from the infundibulum below by a membranous septum. The aorta passed upwards one-half inch and divided into two branches, the right, the larger, going above the right bronchus, having hooked beneath it the right recurrent laryngeal nerve, to gain the right side of the vertebral column. The left passed above the left bronchus, curved downwards, and became the descending aorta. From the right arch ascended the common carotid and the subclavian in the order named. That on the left gave off the innominate, which in time gave off the common carotid aud the subclavian. It then continued as a large artery, corresponding with that on the right side, but smaller in calibre, terminatiag be-

*Treatise on Electro-Diagnosis.

hind and below the bifurcation of the trachea in two parts, each subdividing into numerous branches, carrying the blood supply to each lung. No trace of the ductus arteriosus could be found. Other viscera normal. The mother of this child was markedly strumous, which is given as a cause of this malformation. She could recall no fright which could have been blamed with the causation of the trouble.

In the majority of cases where a post mortem examination is made, the pulmonary artery is found to be either obliterated or greatly lessened in its calibre, and the septum ventriculi is absent in its upper part, allowing the two ventricles to open into one common artery. Clubbing of the fingers and toes is noticed, especially in those who have lived for some time. Dr. Norman Moore, pathologist to St. Bartholomew's hospital, has made microscopical examinations of these clubbed members, and reported his findings to the Pathological Society of London. He finds it due to engorgement and slight thickening of the walls of the vessels. Females who live to maturity, and a few who attain adult age, do not have the flow of the menses until late. The youngest on record is 16 years. One cyanotic woman is on record as having borne two children.

IS CHLOROFORM IN PARTURITION A WORSE THAN USELESS AGENT?

BY J. H. HOBART BURGE, M. D.,

Of Brooklyn, N. Y.

Dr. Melsheimer, of Indiana, answers this question in the affirmative with such positiveness that we would think there was nothing more to say. Such honest and earnest articles as that of Dr. Melsheimer in the Reporter of November 13 always do good. Such a plea for conservatism, and such a warning against the free and indiscriminate use of an agent so fraught with danger as chloroform by inhalation has my hearty approval. Nevertheless my personal experience with this agent leads me to regard it as of inestimable value in promoting parturition. All that Dr. Melsheimer says is true from his standpoint, but there is another view of equal importance, which I think we cannot afford to overlook. Let it be remembered that Dr. Melsheimer's argument is against the universal and free use of chloroform for the purpose of enabling women to have children without the painful consciousness of uterine contractions. This view I heartily endorse, and I would as heartily emphasize the assertion that the careful administration of chloroform by inhalation in the latter part of the first stage of labor is a measure of such value, not merely in lessening the sufferings of the patient but in promoting the labor and hastening the favorable issue of the case, that in the experience of thirty years in its use I am more and more impressed with the fact. When the labor is well established and the pains vigorous, it often happens that the effect of the uterine contractions is so agonizing, so "cutting," that the patient's will is exerted in struggling against the natural result. Now is the time for the chloroform to do its best work, and you can rely upon it almost every time. Just before the pain comes only say to the patient, "Just breathe a little of this, and it will take off the sharp edges of the pain, so that you can bear down without hurting you so badly," and the difference in the amount of distress is immediately so great that from that moment the progress of the labor is seen to be rapidly accelerated. If the practitioner finds by its effect upon the pains that he has erred in judgment and given the few whiffs of chloroform before the case was ready for it, the very little respite which it occasions in the sufferings of the patient will in the long run prove advantageous; but let him now delay its further use till a somewhat later period.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

Service of Dr. J. H. Packard.

Removal of Enlarged Cervical Glands.

I bring before you to-day this patient from whom one week ago you saw me remove ten cervical glands which were enlarged and suppurating. He is a mulatto, twenty years old, and of undoubted specific taint.

There is always more or less danger attending this operation. I recall a case in the hospital where the operation was urgently called for and carefully performed. The patient did well for a time, but eventually began to fail and died, not from blood-poisoning, but from general deterioration of the system. Clinical experience teaches that it is particularly dangerous in those of mixed blood; the mulatto's system is less reliable than that of the full-blooded negro.

I therefore felt some reluctance in un-

dertaking the operation for this patient, who, in addition to a bad family history, had suffered from protracted suppuration. However, something had to be done, and last week I removed the enlarged and broken-down glands. While operating I discovered a large hidden abscess in the region of the parotid, which, by use of the probe, was made to communicate with the suppurating glands.

The wound was thoroughly washed out, and then packed with strips of lint saturated with balsam of Peru. From the day of the operation he has been doing well, and I show him again to-day that you may observe for yourselves the good result.

The open surface is a nicely granulating one. Suppuration has ceased, and the patient's general condition much improved. We may justly call the operation a success.

In addition to this he was placed on antispecific (mixed) treatment, which will later give place to potass. iod.

In removal of enlarged glands, it is well to use a short-bladed blunt knife, otherwise in dissecting under a gland we cannot avoid the danger of wounding the neighboring vessels and nerves.

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

Stated meting October 22, 1886.

Dr. Clara Marshall in the chair.

Dr. Clara Marshall reported a case of

Ovariotomy

as follows:

Hanna B., æt. 55, single, resident of Philadelphia, was admitted to the gynecological department of the Philadelphia Hospital the latter part of August, 1886. Previous to that time I saw her in the medical department in consultation with Dr. E. T. Bruen, who had already made the diagnosis of ovarian cyst, and through whose courtesy the patient was transferred to the gynecological wards. The patient's mental condition being below the normal standard, it was difficult to obtain a reliable history of the case. However, her statement was something as follows: Her father and one sister died of "heart disease," her mother of "old age," one sister and one brother died of "dropsy." She had one brother living and well. As a child she was sickly, but since that time, with the exception of the past year, she had been in fair health.

Early last winter she noticed that both lower extremities were beginning to swell; subsequently the abdominal enlargement was observed, which increased rapidly until it reached its present size.

Upon admission, the left leg only was swollen (pitting distinctly upon pressure), and the abdomen was larger than at the end of gestation.

The heart, lungs, and liver were normal, and analysis of the urine yielded negative results. The patient was emaciated, and her circulation was feeble, the extremities being of a somewhat venous hue, and cold to the touch; bowels regular, appetite poor.

Special attention was given to improving the patient's general condition. She was given nutritious and generally liquid food; flannel undergarments were ordered; the nurse was directed to give a warm bath every other night, followed by brisk friction. She was given quinine sulph. gr. iij three times daily, also Basham's mixture as a diuretic tonic. Under this treatment the general health improved, and the patient described herself as feeling much more comfortable. Previous to the day fixed for the operation great care was taken to free the operating-room from infection; the walls and floors were washed with a solution of the corrosive chloride of mercury, the walls were then white-washed (corrosive sublimate being added to the white-wash), every article of furniture in the room was washed with a solution of corrosive sublimate, and finally the room was tightly closed, and fumigated with sulphur. The instruments were disinfected with carbolic acid; all other articles, including sponges and towels, were boiled in a solution of corrosive sublimate. On September 23, 1886, at 11:40 a. m., the patient being etherized, the operation for the removal of the cyst was begun, with the assistance of Drs. Parish, Stryker, Richardson, and McLaughlin, and in the presence of several members of the resident staff. An incision three and one-half inches in length was made in the abdominal wall between the umbilicus and symphysis pubis, and the tissues were divided until there came into view a cyst, which proved to be a multilocular cyst of the right ovary, free from adhesions. The patient was turned upon her side, an incision made in the cyst, its contents evacuated, and the tumor drawn through the incision. The pedicle was ligated after the method of Lawson Tait, and after the cauterization the stump was dropped into the abdominal cavity. The wound was closed with black silk sutures, and dressed antisep-

tically, the dressing being secured by adhesive strips and a flannel binder. The weight of the tumor was 65 pounds. Immediately before the operation the patient's temperature was 100° F., pulse 90. During the operation the pulse was steady, and varied between 80 and 96. Shortly after the conclusion of the operation, pulse was 100, temperature 99⅘°. There was no vomiting either during etherization or subsequently, and reaction was perfect; the patient dropped into a quiet sleep, from which she aroused occasionally and complained of nausea, which would either pass off of itself or was quickly controlled by a hypodermic injection of gr. ⅛ morph. sulph., and at 6 a. m. the following day she was fully conscious of all her surroundings, and seemed to show more intellectual acumen than ever before. For the first thirty-six hours the temperature ranged from 99.4° to 100.4°; pulse 96 to 100; respirations 20. During the latter part of the second day the temperature rose to 102.2°, pulse 94, and the patient complained of severe pain in the right iliac fossa. By the third day a cough was developed, and the abdomen was decidedly tympanitic. The temperature under the influence of quinine and cold sponging was reduced to 100.2°, only to rise again, reaching on the fourth day 104.8°. In spite of the rise in temperature the suffering was not great, comparative freedom from pain being secured by means of opiates. But on the fourth day all the symptoms rapidly increased in severity, and death took place in exactly four days from the date of the operation.

The post-mortem examination (made by Dr. Wm. Osler), while revealing septic peritonitis as the direct cause of death, showed, also, certain other factors in the case, some of which were entirely unsuspected. The following extracts from the report are of interest:

Abdomen.—The wound in the abdominal wall looks healthy, and has united by the first intention. Peritonitis in the lower region of the abdomen. Lymph glues coils of intestines together, and to the abdominal walls; not much effusion. Pus in the right iliac fossa. Slight amount of bloody serum in the pelvis. The most extensive inflammation is in the neighborhood of the right broad ligament. Moderate injection of vessels over coils of intestines.

Kidneys.—Left is represented by a small, firm, hard organ, greatly contracted; only a small portion of normal tissue remains; weight less than one ounce.

Thorax.—Evidences of a recent pleurisy in the lateral region of the left side.

Lungs.—Left lung: crepitant, except at lower lobe, which is heavy, airless, and deeply œdematous. Right lung: Posterior part of middle lobe solid; lower lobe dark in color, deeply congested, and presents several patches of lobular pneumonia; no suppurating foci.

Pelvis.—Uterus closely adherent to right wall of pelvis. Thick layer of lymph covers attachment of pedicle. Ligature is firm; its line infiltrated with pus. Inflammation is curiously limited to fascia covering psoas and part of transversalis muscles. Anterior surface of uterus shows no lymph, but upper margin presents a thick, dense layer. Right broad ligament infiltrated with bloody serum. Left ovary and tube normal. Orifice of left internal iliac vein obliterated. The left common iliac, left external, and the internal iliac veins are occluded by old thrombi; these thrombi being densely adherent.

In the discussion which followed the reading of Dr. Walker's paper (see page 33), Dr. Emma Musson spoke of having used turpentine in a case of chronic bronchitis in which the ammonia salts had been used without benefit. The case was one of some years' standing, but has improved since using gtt. v of turpentine three times a day for three or four weeks.

Dr. L. Brewer Hall: "Turpentine is extensively used in diseases of the ear, nose, and throat. As a styptic, oil of erigeron is better than turpentine, being more rapid in its action and more pleasant to take. Turpentine is a stimulant to the kidneys as well as to other organs, the waste matter being thrown off by these organs, and the lungs being greatly relieved thereby."

Dr. Clara Marshall said she had seen the good effect of turpentine in the chronic cough of old persons where there was a great amount of expectoration; the drug seemed to act as a *general* stimulant, as well as a stimulant to the mucous membrane. She also mentioned a case of intestinal catarrh, where there were one or two loose stools a day, accompanied with great pain, which was greatly benefited by oil of turpentine in gtt. v doses three times a day. Oil of gaultheria or spt. of lavender will cover the taste of turpentine.

Dr. Louise S. Blum spoke of a case of gastric ulcer which was cured by the use of turpentine and artificially digested food. The oil of turpentine was used in emulsion with oil of gaultheria to cover the taste.

Dr. A. Victoria Scott is in the habit of

giving turpentine in typhoid fever to relieve the flatulence. In one case, while using it for this purpose, the patient expelled a tapeworm.

Dr. Scott uses inhalations of turpentine in bronchial affections. She has never found the drug to act favorably in hemorrhages from the kidneys or uterus, and in such cases uses ergot or oil of erigeron.

Dr. Walker, in closing the discussion, said: "As turpentine is an irritant to the kidneys, I would not use it in hemorrhages from those organs. On the vaginal and uterine mucous membrane turpentine has no effect, as it does not come in contact with them. I prefer the spirit or oil of turpentine, especially in pulmonary affections; it is more quickly absorbed and disseminated to the seat of disease."

Mary Willits, M. D.,
1527 *Green St.* *Reporting Secretary.*

NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, December 7, 1886, C. L. Dana, M. D., president, in the chair.

A Case of Progressive Muscular Atrophy, with Bulbar Symptoms.

Dr. W. R. Birdsall presented the patient and read the history of a "Case of Progressive Muscular Atrophy, with Bulbar Symptoms." The atrophy limited to the left upper extremity, the abductor indicis of the right hand and the tongue, the latter affected bilaterally — predominently on the left side. He presented the case as illustrating the nonconformity of disease to our arbitrary standards of classification and description of types of disease.

The patient showed peculiarities due to the pathological process having advanced to an extreme degree in certain regions, while its distribution had remained limited, not involving neighboring parts usually affected; the left upper extremity and tongue being the parts involved, and to a marked degree, while the right upper extremity was normal, excepting the abductor indicis; the trunk and lower extremities remained healthy. A detailed history of the case was given, the patient being a carpenter, a Swede, aged 39, married, of temperate habits, without a history of syphilis or other disease. A chart was presented showing the electrical reactions.

Dr. E. C. Seguin had seen very few examples of unilateral progressive muscular atrophy. He had at present one patient under observation, in whom the muscular atrophy was limited to one side, presenting the electrical and other characters of progressive muscular atrophy.

Dr. W. M. Leszynsky had a girl aged seventeen under observation in whom the atrophy was unilateral, affecting only the supra-spinatus, deltoid, and a portion of the trapezius.

Self-Abuse in its Relation to Insanity.

Dr. E. C. Spitzka, the author of the paper, after citing the views of the classical writers, stated that the question of the existence of a special form of insanity, due to self-abuse and to nothing else, was complicated by the existence of another well-demarcated affection known as the insanity of pubescence. The mental diseases due to self-abuse usually occurred at the same period of life as the latter disorder. This fact explained the similarity of many clinical features between them. The question was further complicated by the fact that hebephreniacs—sufferers from pubescent insanity—are often addicted to self-abuse, and that thus the features of one disorder may be engrafted upon the other.

The continental authorities do not recognize a special form of masturbational insanity in their tables. Schüle, it is true, speaks of *onanistic insanity* in the sense in which Maudsley uses that term; but he assigns no part to it in his classification, and disposes of it in a few lines. Kraft-Ebing recognizes the vice as an etiological factor, and speaks of such and such forms of insanity on a masturbational basis. He, as well as Schüle, with the majority of recent German writers, follows Ellinger in attributing to the *masturbatory neurosis* a relation to the development of insanity analogous to heredity and other admitted predisposing and determining factors. I have yet to find any dissent expressed by these authorities from the position taken by Emminghaus, who claims that owing to its causal relationship to widely differing forms of insanity it is not proper to speak, as Skae does, of a special form due to masturbation. This critical remark would seem to be supported not only by the clinical facts accessible to every observer, but also by the confusion existing among those writers who have attempted to define and demarcate such an affection. Skae speaks of a peculiar imbecility and shy habits as characterizing the disorder among the youthful, and suspicion and fear, and scared looks, palpitation and feeble bodies as found in older victims, who gradually pass into dementia. The most distinguished follower of Skae attributes the

following symptoms to that form of insanity of which masturbation is the chief cause and "the chief symptom present," giving "the whole case distinct features." Exaggerated self-feeling, conceited, shallow introspection, frothy, emotional religious notions, and a restless, unsettled state, with foolish hatchings of philanthropic schemes. Luther Bell, who, with Isaac Ray, was among the earliest to attribute special symptoms to insanity caused by masturbation, furnishes a very faithful picture of certain cases, whose particular feature he describes as being a tendency to dementia, a loss of self-respect, a sulky, mischievous, and dangerous disposition, and a subjectively irritable and depressed state of mind. Griesinger, who does not recognize a special form and denies specific characters, admits that the majority of cases are marked by a profound dullness of sentiment and mental exhaustion, by religious delusions and hallucinations of hearing, and a rapid transition to dementia in the event of incurability, which latter is the usual issue.

The effect of masturbation on the mind and nervous system varies according to the age at which it is commenced. Like other agents which are injurious to the developing brain, such as epilepsy, alcohol, and syphilis, its effect is most rapid and serious in younger children, less so in adolescents, and least marked in adults, unless protracted. For very young infants it causes a profound deterioration, manifesting itself in convulsive, choreic disorder, and imbecility. In those who masturbate between the fifth and tenth years the effects seem to be manifested chiefly in arrested brain nutrition. Spontaneity of thought and action is absent with such children; they do not play as their comrades do.

There are a number of other circumstances which modify the development of mental disturbance in masturbators. The age between twenty and thirty-five is preeminently the period of somatic introspection. It is at this period, if at any, that the average man begins to think about his bodily condition. In these years men weigh themselves, discover that they have too much or too little flesh, develop slight gastric or intestinal disorders, reflex nervous symptoms, or indulge to excess in tobacco, in baccho, and in venere, and consequently are on the qui vive for the occurrence of cardiac, renal, or venereal disease, or of sexual disability. It is at this period that the results of masturbation are most deeply felt by a large proportion of the victims of that habit. The prevalent tendency of his age and of his associates of the same age carries him into a veritable nosomania. Perhaps also he attempts under lay or medical advice to accomplish coitus, and fails. It is for this reason that we find the larger portion of cases of insanity due to masturbation developing between the twenty-fifth and thirty-fifth year, classified as "hypochondriacal paranoia."

A number of typical histories were then related, from which the author drew the following conclusions:

1. Self-abuse is an etiological factor in a large number of cases of insanity, but only those cases should be designated as insanity of masturbation in which the connection between the excesses and the symptoms is direct.

2. Self-abuse, to produce insanity, must have been carried very far, or the subject must be predisposed. Often onanism can be traced in other members of the family, and very often it is found that the maternal ancestry is a weak one.

3. Mania, melancholia, and epilepsy occasionally occur in young masturbators, the former two usually having a favorable prognosis.

4. Stuporous insanity and katatonia are both common, and the former presents good prospects.

5. The forms thus far mentioned when occurring in masturbation present no essential differentiation from the typical psychoses. They should therefore be designated as mania, melancholia, stupor, etc., *from* masturbation, and not as masturbational insanity.

6. There is a chronic delusional insanity in grown persons who have been devotees of self-abuse, and it is usually a hypochondriacal *paranoia*. Clinically it is very like typical paranoia, and etiologically it is not the direct result of self-abuse, but rather of an intermediate neurosis—a cerebro-spinal irritation which is due to self-abuse.

7. Finally, there is a form of insanity developing about or after the period of puberty which does merit the name "masturbational insanity." It is chronic, has a tendency to agitated dementia, is characterized in its early period by anxiety, timidity, suspicion, fear, and a cowardly mean disposition. Later there are confusion, meddlesome, aggressive behavior, vague delusions, loss of memory, and finally deterioration. After these are observed spells of fury or destructiveness. This form is never due to any other cause, and resembles no other form of insanity than the one already alluded to.

8. It is not always possible to differentiate between the insanity of pubescence and the form described. But where the former disorder is uncomplicated by the latter, it may be known by a history of peculiarities in infancy and childhood, by the greater constancy of the mental state, which in onanists is exceedingly variable. Hebephreniacs are more apt to be expansive in their notions, more inclined to favor projects of a chimerical character. In other words, insanity of pubescence is the paranoia of adolescence, and masturbational insanity the pre-senile dementia of the same period of life.

Dr. Ralph L. Parsons made some remarks with reference to the treatment. The diet should be principally vegetables and milk, with little heat and stimulating condiments. As the patient sought solitude, he should be thrown as much as possible with others, not alone of his own sex, but also of the opposite sex. He should be kept occupied, and manual labor of some form, like farming, was best. He knew of no special benefit to be derived from medicinal treatment, as with the bromides, or with the application of irritating substances to the penis. Cutting off the prepuce might be of advantage in some cases. The patient should be closely watched day and night; mechanical appliances might sometimes be necessary; moral influence could be depended upon to a certain extent.

Dr. Kellogg agreed with the author in the conclusions arrived at in the main. But he would like to know Dr. Spitzka's views as to the relative importance of artificial sexual indulgence and indulgence in the natural manner, as factors in the production of insanity. Masturbation was a wide term, and ought to be defined. The effects in some cases were more observable in spinal lesions, in others in cerebral lesions. He believed that masturbation itself was not capable of producing insanity in a person of sound heritage. He was convinced that it was capable of suspending mental growth, and producing forms of imbecility in those of sound parentage. He knew it could produce insanity at the time of pubescence, and there were persons of mature age who had a predisposition to insanity in whom the attack was excited directly by sexual excess. Occasionally persons indulged to excess for a year or two only, as did sailors sometimes when on long voyages. Masturbation was also capable of producing insanity in old persons who were on the decline; it hastened dementia. He did not think there was a peculiar set of symptoms; the age of the patient, his education, his heritage, his whole mental make-up, influenced the symptoms more than the exciting cause. He did not believe it possible to separate masturbation from other forms of sexual excess, and the title "sexual abuse" would have been more appropriate because more comprehensive than self-abuse.

Dr. Noyes said the case referred to by the author as having been cured was the only one in Bloomingdale Asylum in which a cure had been effected, and he attributed recovery in that case to transferring the patient to a farm, where his whole mode of life, including diet, was changed, and for the better.

Dr. L. C. Gray thought the author had given an accurate description of the mental disturbances often seen associated with the habit of masturbation, but he asked if he did not also find similar mental disturbances in indiduals who were not masturbators.

Dr. Spitzka replied that in individual cases he had, but not in groups of cases, as occurred in masturbators.

Dr. Gray had seen the mental disturbances described in patients addicted to masturbation, but he had been unable to decide to what extent masturbation could be considered as a cause or simply an associated habit. He had two cases in mind in which that group of symptoms were followed in the course of a few weeks by masturbation in individuals who had not previously been addicted to self-abuse. He had seen the same symptoms follow excessive sexual intercourse. He had in some cases noticed very exaggerated and extensive cremaster reflex.

In closing the discussion, Dr. Spitzka said that there were undoubtedly some forms of sexual vice which were physically as injurious as onanism. But he had not seen a sufficient number of cases to enable him to say anything about their mental sequelæ unless he cared to risk being premature. He had known epilepsy and stupor to follow natural sexual excess in a young person, and paretic dementia in more than one cunnilinguist and sodomist. The form he had sketched was, as far as his experience went, only found in masturbators. While he admitted with Dr. Kellogg that the single act of onanism was physically not a formal thing, and not much if anything different from normal coitus; there were two respects in which the onanist and libertine differed most widely, one has a moral, the other a physical feature. The onanist practices a secret crime, the social and gregarious element is excluded. Knowing that his act is despised, he becomes inclined to suspicion and fear of discovery.

A libertine cannot exceed beyond a certain limit. Coitus requires a certain condition of the organs which implies the existence of certain normal energies. When these fail, the limit is set to further excess. With the onanist it is much different. There are masturbators who require no erection; yea, who succeed in their injurious act without any manipulation. The consequence is that they pass far beyond the limit set by nature to natural excess, and no calculation can be made of the damage done.

Dr. Parson's dietary propositions were endorsed by the highest authority. Individually the speaker was not decided in his own mind whether a highly nutritious diet would prove injurious in certain phases.

CLINICAL SOCIETY OF MARYLAND.

Stated meeting held November 19, 1886.

The President, Dr. Randolph Winslow, in the chair.

Dr. L. McLane Tiffany reported a

Case of Angioma of the Right Upper Extremity.

It occurred in a child 5 years of age, whom he first saw two years ago. The tumor was a congenital angioma involving the right hand and dorsum of the right forearm. The hand was very much deformed. There were several enlarged glands in the axilla. The child was occasionally ill, and at these times the growth became of a purplish hue.

The treatment was begun by inserting into the tissue at different points threads of silk that had been soaked in a solution of tartar emetic. Improvement began, but after about two years she returned with the growth as bad as it originally was.

The treatment that was then instituted was the use of the thermo-cautery.

The growth on the hand presented itself in the form of nodules of larger or smaller size. Crucial incisions were made into these swellings, and their interior thoroughly wiped out with the heated knife.

The wound was cleansed and dressed, and the dressing was not removed for more than three weeks. The result was all that could be desired.

After about two months the operation was repeated upon the other nodules on the back of the hand and the dorsum of the forearm, and excepting a temporary delay caused by the accidental interference with the dressing, the wounds also healed kindly. Of the two sittings, the first was the more satisfactory. It was entirely painless. There was no sloughing other than the small amount caused by the cautery.

Discussion.

Dr. I. E. Atkinson called attention to the great variation in size, character and development of these tumors. They range from the smallest innocent nævi to the large cavernous angioma just referred to. He has had very little experience with the large forms that have just been described by Dr. Tiffany, but of the smaller commoner varieties, such as the "port wine" marks, he has seen a large number. The most of these growths tend toward self-limitation, but this is sometimes not reached until much deformity has resulted.

The commoner forms of the angioma are superficial, and do not go deeper than the skin; but the larger varieties, as was seen in Dr. Tiffany's case, are located deeper down in the fasciæ.

The treatment in these cases that has given him the greatest satisfaction is the introduction into them at different points of threads soaked in deliquesced caustic potash. These threads are reinforced as sloughing progresses, until the whole growth has sloughed away.

A common objection to this treatment is the danger of emboli formations which may get into the circulation and cause trouble. Where caustic potash is injected into the growths in a fluid condition he thinks the possibility of such an accident very great, but where threads soaked in the solution are employed he thinks the action localized to the neighborhood of the thread, and moreover the action is so gradual that he thinks that the element of danger from emboli is almost entirely eliminated. It has in his hands always given the most favorable results.

Dr. Randolph Winslow asked Dr. Tiffany if he understood him to say, in speaking of his case, that there could be no healing of a wound without the formation of pus?

Dr. L. McLane Tiffany replied that it depended entirely upon what Dr. Winslow meant by pus.

Dr. Randolph Winslow. If antiseptic precautions are properly observed there can be healing of a wound *absolutely* without pus.

Dr. L. McLane Tiffany said it was his opinion that in all such cases there was an exudation of liquor sanguinis, holding in suspension a greater or smaller number of leucocytes. He was not prepared to say

just what the relative number of leucocytes should be to constitute what Dr. Winslow meant by pus.

Dr. A. K. Bond asked Dr. Tiffany if the cautery acted upon the whole growth at once, or only at the points of application.

Dr. L. McLane Tiffany said its action was localized to the parts to which it was applied. It caused shriveling of the veins.

Dr. L. McLane Tiffany then reported a

Case of Inflammation of Appendix Cæci with Perforation.

It occurred in a man æt. 28 years. He saw the patient in company with Dr. Henry M. Wilson, on the sixth day from the time that Dr. Wilson had first seen him. He found the patient with a fluttering pulse, surface cool, pain in the belly, and, in short, in a collapsed condition. Reaction was not established until after three hours. When it did set in, the belly became smaller and everywhere tympaaitic. For the past six months the patient had been complaining of pain in the abdomen. It was not referred to any fixed point.

The patient was kept quiet by the use of opiates. After the first collapse the pulse did not rise above 100, neither did the temperature go above 100° F.

On the next day the patient complained of intense pain in the penis. Pressure over the belly caused pain.

On the sixth day the diagnosis was made that there was a foreign body in the appendix cæci, and that perforation had taken place. The pain in the penis was so great that perforation was thought to be intra-pelvic, and that the bladder had become involved in the inflammatory process.

General peritonitis was excluded by absence of elevation of the abdominal surface temperature. Laparotomy under the circumstances was not considered advisable.

On the following Sunday (13th day) fluctuation was detected in the left inguinal region. There was a swelling from which pus was drawn with an aspirating needle; the opening was enlarged with a knife and a qnantity of pus evacuated. The cavity was then washed out and drained with drainage tubes.

The patient died that night, having been delirious since the preceding Wednesday. A diagnosis of septicæmia had been made.

Autopsy revealed a mass of intestines glued together by plastic exudation, and forming part of a cavity that encysted a quantity of pus, which lay in the region just behind the pubes. A bit of hardened non-nucleated fecal matter was found in the pelvis, but the point of perforation was not made out.

The pus was incysted in such a way and in such a position that it was impossible to have reached it from without.

He thought the localized peritonitis due to the presence of the foreign body that must have been there for some time.

Dr. N. G. Kierle asked Dr. Tiffany to describe in detail the appearance of the appendix cæci.

Dr. L. McLane Tiffany could not do so, as he did not do the autopsy himself, and the dissector had cut the appendix off. The dissector did not find an opening in its walls. From what he could make out, Dr. Tiffany thought the appendix the point of origin of the abscess, which in time arose from the necrosis of the appendix walls.

Dr. N. G. Kierle thinks too much stress is laid upon the presence of foreign bodies in the appendix cæci. The histology of this tissue indicates the probability of its taking on an idiopathic form of inflammation. Many of these cases respond favorably to treatment.

Dr. I. E. Atkinson thinks the presence of hardened fecal matter in the vermiform appendix a common observation, and they do not always give rise to perforation. The diagnosis is not always possible, but many of these cases indicate their nature by swelling and pain over this region. There is likewise an œdema of the neighboring soft tissues consequent upon the ulcerative process.

He don't consider the sudden appearance of tumors in this region always an indication for operation. Many of these cases recover under therapeutic treatment.

The diagnostic points in perforation of the appendix he thinks are pain in the locality for a few hours, collapse, and a general or localized peritonitis.

He thinks where operative procedures are resorted to, that chances for success are proportionate to the promptness of the surgical aid.

Thinks many cases of perforative appendicitis can be saved by early and judicious operation. He believes that perforation does sometimes occur without proving fatal.

Dr. N. G. Kierle: Fitz considers perforation of the appendix cæci one of the most fatal of accidents. If the irritating particle is in the cæcum or in the ascending colon, the anatomical arrangements of these parts permit of two results: either perforation into the peritoneal cavity, or abscess in the cæcal tissues. He has seen fatal results from

asthenia in patients in whom there was a slowly growing abscess in these tissues. These cases may go on without any peritonitis whatever. But in the appendix we have a different arrangement of the parts. Here this bit of intestine, over the whole of which the peritoneum is reflected, hangs directly within the peritoneal cavity. Perforation or inflammation can not, therefore, occur in its walls without involving the peritoneum, with production of more or less of peritonitis.

Dr. L. McLane Tiffany thinks the points made by Dr. Kierle very important. Thinks the anatomical arrangement of the parts makes a great difference in the pathological possibilities. If operation is to be done after perforation, it should be instituted immediately after the patient reacts from the collapse.

He don't advocate operation in all cases. Thinks the fatal results in abdominal sections often due to the handling of the intestines.

In perityphlitis we have time to wait. In appendicitis action must be prompt.

Periscope.

Calendula.

Dr. R. G. Reynolds thus writes in the *Pacific Med. and Surg. Jour:*

This plant, the common marigold of our gardens, has been used as a medicine for a great number of years. It used to be considered anti-spasmodic, sudorific, deobstruent and emmenagogic, and was given in low forms of fever, jaundice, amenorrhœa, etc. But its effect in any of these complaints was very uncertain, if of any benefit whatever, and so it gradually fell into disfavor and disuse. The 14th edition of the U. S. Dispensatory gives it a place and a very short notice in the list of unofficinal remedies, and the 15th edition, being more favorable to its claims, places it in the officinal list, but has nothing to say in its praise. It says in the days of therapeutic darkness, it was thought to have medicinal virtues which have faded into oblivion in these latter days of light and knowledge. It barely mentions that a tincture is made from it which is used as an embrocation, to which it is gracious enough to ascribe healing powers about equal to simple alcohol. So if we had no other encouragement for the use of the plant than the U. S. Dispensatory, we would be likely to give it a wide berth.

In 1868 Dr. A. Livezay published a paper in the Medical and Surgical Reporter of Philadelphia, stating that he was in the habit of using a strong tincture of the flowers as an application to incised, lacerated and contused wounds, and invariably found it to have a curative influence, preventing inflammation and suppuration, and promoting the healing of wounds by first intention when the wound was properly adjusted. Since then there has been occasional favorable mention of it by writers in the medical journals, and it began to grow more in favor the more it was tried and written about. My attention was first called to it about the year 1880, by some writer whose name I forget, and so favorable an impression in its favor as an embrocation was made on me that I determined to give it a trial. I know of no better way to emphasize its virtues than give the history of a few cases wherein it has proved to be a remedy most potent for good.

The first case in which I remember of giving it a trial was that of G. G. Murdoch, who came to me with a deep lacerated wound in the palm of the hand, produced by the head of a horseshoe nail being plowed through the hand by a vicious horse. The wound was very ragged, and about as unfavorable one to expect to heal by first intention as it is possible to conceive of. I thought this a good case to try the virtues of calendula. I made a tincture from the fluid extract made by Parke, Davis & Co., by adding three parts of alcohol to one of the extract, and after adjusting the wound carefully, and securing it with adhesive strips, I covered it with lint saturated with the tincture, and gave him particular orders to never allow it to get dry, but keep the lint constantly saturated with the tincture. He followed the instructions carefully, and in ten days he presented himself with the wound perfectly healed, and informed me that not one drop of suppuration had taken place. I considered this remarkable, considering the ragged character of the wound.

Another rather important case was that of Thomas Tallman, who, in a fight, received a

knife wound in the face. High up on the temple in the edge of the hair the knife was thrust in to the bone, and then drawn down close by the eye through the cheek, clear down to the middle of the chin. The cheek lay open fully an inch, and he presented a ghastly spectacle. I adjusted the wound very carefully, and secured it with interrupted sutures, and applied a decoction of calendula made by diluting the fluid extract with three times its bulk of water, with instructions to keep the wound constantly covered with lint saturated with the solution. In fifty-six hours I removed the sutures and found the wound well united by first intention, and in less than two weeks he was around well, not a drop of suppuration had taken place except high up in the temple where a small artery was cut, and I had to apply Monsel's solution to arrest hemorrhage. The consequence was, that the wound, though a desperate one, healed almost without a scar, a very narrow red line being all there is to mark the track of the knife, a very important consideration to the patient, as the wound was in such a very prominent place.

But a much more important case occurred in the summer of 1885. One night, while peacefully sleeping, a man rushed to my door and commenced ringing the bell as if he were turning the crank of a coffee mill, and on my answering, he told me to hurry up to the saloon, as James Purkerm had just shot his brains out. I thought of his brains were shot out there was no great need for haste on the part of the surgeon, as I knew of no way by which I could return them to the cranium, so that they might again perform their functions. However, I dressed as quickly as possible and started up, not thinking it was worth while to take my medicines with me. On the way I met another messenger calling on me to hurry up, as he was still living. I then turned back, and getting my medicines hastened to the scene. I met a ghastly sight. The man was lying on the bed in a pool of blood; a bullet from a 44 calibre Colt had entered the face just in front of the left ear, half an inch below the line of the eyes, and ranged upwards and forwards, emerging through the right eye, and obliterating the eye-ball. He was unconscious and very weak from the shock and loss of blood. He would only regain consciousness when the stomach would become overloaded with blood and had to be vomited, which would take place about every half hour. The pulse at times would flicker, and I thought sometimes the end was just at hand. But towards morning he began to show signs of rallying, and I concluded I was after all going to have a case to treat. I then prepared an infusion of calendula, one part to three of water, and kept both wounds carefully covered with the wet lint, and enjoined constant watchfulness so that they would not be allowed to get dry. I visited him twice daily, but never found any cause to change the treatment. Fearing I would run out of the medicine, I ordered by express six bottles from San Francisco, and received them with the information that that was all that could be found in the city, and this is probably the main cause why you are afflicted with this paper. I concluded that if such a small stock was kept in San Francisco, surely the profession did not appreciate its virtues. In ten days I had him sitting up comfortably, and so far not a drop of suppuration from either wound after he commenced sitting up; there was one day the attendant had permitted the bandage supporting the lint to bulge out, and the wound to dry, and a superficial suppuration immediately began in the wound in the cheek. I carefully squeezed out the pus and filled the wound with the mixture, and enjoining more care in future, there was no more of it.

In three weeks he was riding around, discharged and well, and but for the loss of his right eye, apparently as well as before he received the wound.

I consider this case peculiarly interesting on account of the size of the ball, the closeness to the brain, the spongy character of the bones penetrated, and the destruction of the eye. I firmly believe that had this wound been permitted to heal by the old method of suppuration, blood poisoning would have been inevitable, and the well eye would have been also in great danger from sympathetic inflammation; so that I consider the man owes his life entirely to the flower we thought so pretty in our boyhood days, the golden marigold.

Obstacles to Fecundation.

The *Med. Age* says: The perpetuation of his species is one of the most imperative duties which man owes the state. While in some instances this duty is so religiously observed as to have won to the teachings of Malthus many adherents, the devices of the brothel have been so freely introduced into classes of society which stand most in need of multiplication, as not only to have practically nullified the divine decree to multiply, as far as they are concerned, but

also to have excited in the females of the same an amount of disease which has made gynecology one of the most profitable of the medical specialties. In the majority of instances of sterility the exciting cause has been the means which were employed early in the married life to prevent conception until "a more convenient season," when the desire and cares of society should be less keen, or, possibly, when the state of domestic finances should better afford the expense of a family. The majority of the cases which consult the physician for the relief of sterility are traceable to these causes. Nature having been thwarted for a number of years, refuses to respond to the desire when children are wanted. The physical condition in these cases is found to be chiefly a catarrhal condition of the uterus. In a report of one of Prof. Pajot's lectures given by Dr. Thomas Linn, Paris correspondent of the *Philadelphia Medical Times*, it is stated that of twenty couples who consult the physician because of sterility, ten or twelve of the women will be found to have uterine catarrh, due, doubtless, to the cause above mentioned.

The Professor gives also an analysis of the other causes of sterility. Among others is the narrowness of the external orifice of the neck of the uterus, this narrowness being usually associated with a peculiarity of form, the uterus having the "top"-shaped os, or the conical os of Sims.

The third most frequent obstacle is the one most talked of by charlatans and ignorant medical men—they are versions and flexions. The normal uterus presents a certain degree of anteversion nearly in the axis of the superior strait. If this is exaggerated, there is an anteversion; the contrary state is retroversion, and the lateral inclined is lateroversion. Pregnancy brings a light lateroversion, the neck being on the left side. Flexions are much the same in name; but it is curious, says Pajot, that the versions are greater obstacles than the flexions. That certain kinds of apparatus may give comfort is possible in these cases, but as to real cures they are all useless. He does not speak at present of prolapsus. We don't cure these deviations, because they are not maladies; they are infirmities. These women are no more ill than a person who is left-handed, unless there is also a catarrhal state, or a congestion, or an ulceration. Many women have a deviation without knowing it. It certainly very often constitutes an obstacle to fecundation—one reason being that the *cul-de-sacs* formed make a false route for the male organ, and complicate the difficulty of fecundation.

Acidity of the vaginal mucus seems also to be a cause of the rapid death of spermatozoa. During the last twenty-five years Pajot arrived at a very different conclusion relating to the frequency of fault in the male, than obtained previously, which will astonish you as well as it did me. More than ten years ago he found the proportion of husbands who were the obstacles to fecundation rise to seven in eighty cases. In late years in some four hundred cases in which he examined the seminal fluid, he found one hundred in which the husbands were at fault and the cause of the sterility.

In regard to treatment Pajot has the following which, to say the least, has some novel features: For the catarrhal states, use emollient injections for the first few days, to allay any congestion, and then during the inter-menstrual period—that is to say, not less than ten days nor more than fifteen after cessation of the menses—practice internal cauterization of the uterus, both the cavity of the neck and the body. Use for this purpose my porte-caustic mounted on very flexible whalebone, that cannot perforate the uterus. Professor Richet uses a solid metal one; but in his hands any instrument will do; don't fancy it will do as well in yours. Place powdered nitrate of silver in the little cup, close it with some unguent, and penetrate slowly into the uterus, empty the cup, and the operation is over. If you still fear the porte-caustic, use these little whalebone sticks, which are mounted solidly with a little cotton, carefully wipe out the mucus to get at the real surface, wet the cotton with a little water, and rub it in powdered nitrate of silver, forming a sort of paste, which you can paint over the surface easily. Keep the woman in bed three days or more, and continue emollient injections, and follow them with astringent ones. As to the narrow conically-necked uterus, the best treatment is *dilatation*. I do not believe in Sims' American divider, composed of two blades that are introduced, opened, and drawn towards you, as I have seen fatal results in two cases from its use. No; dilate gradually and largely the *external* orifice only; for, as the other gives passage to the menstrual flux, it will allow the spermatozoa to pass.

I wish now to teach you some therapeutical measures that I think have never been mentioned by any one. When you are advising a woman who has a deviation, see the husband apart. If she has an anteversion, tell her to prepare for the sexual act by not

urinating for five or six hours beforehand, if she wishes to have children. If it is a retroversion, advise as follows: After the monthly period she must eat plenty of eggs and rice, and take a small pill every evening for three or four days (the pill is simply two and a half centigrammes watery extract of opium). During these days she must resist defecation and perform the sexual act. This device is based upon anatomical and physiological facts, and will often succeed in removing these obstacles to fecundation. In one case the full bladder pushes the body of the uterus up, and in the second the full rectum corrects the deviation for the moment.

To give further indications, the professor related the case of a patient who had a left lateroversion, making one of the false routes he talks of. Upon questioning the husband adroitly, he found that the conjugal act was performed in the usual classical manner—dorsal decubitus, in fact—and advised a change by placing the wife on her right side; conception followed and the woman had eventually five other children.

With these different methods he also advises sterile people to have connection *only* about the menstrual period, a few days before and after, and never at other times. As to the husbands with no spermatozoa or with insufficient ones, he advises gymnastics, fencing, swimming, velocipedes, walking, etc., exercise of the inferior members, good living, and continence.

Disseminated Myelitis Accompanying Measles.

The intricate intermixture of disturbances of the nervous system in fevers is receiving wider recognition, and last Tuesday Dr. Barlow brought forward at the Royal Medical and Chirurgical Society (*Brit. Med. Jour.*, November 13,) a case in which acute myelitis had come on during an attack of measles, and proved fatal on the eleventh day. The very scanty record of cases with similar symptoms dates back to James Lucas in 1790, but the pathology has hitherto been an absolute blank. Bergeron, who had one of the very few fatal cases in 1868, could find nothing abnormal after death. The pathological changes in Dr. Barlow's case were excellently illustrated by microscopical specimens and photographs, showing the intense vascular congestion of acute myelitis. Scattered spots were to be seen in the medulla affecting the hypoglossal and vagus nuclei which had shown their presence in life by the patient's inability to control the tongue, to speak distinctly, or swallow easily. That the nervous symptoms were a part of the measles, and not a chance coincidence, cannot be doubted, when any careful survey is made of the concurrence of similar symptoms with exanthemata and acute fevers. The striking and classical essay of Gubler, in 1860, first made that plain, and the subsequent collections of Landouzy and Arenfeld have reinforced it. Westphal's critical genius for a time illumined the subject and drew fresh attention to it, showing in 1872 the special tendency of small-pox towards nervous complications; in England, except after diphtheria, the point has been little noticed. Dr. Wilks's wide experience supplied only one case of nervous lesion (paraplegia) following upon small-pox. Dr. Barlow referred also to two cases of nerve-lesion in small-pox affecting speech, published in the last volume of the Clinical Society's Transactions by Drs. Whipham and Myers. They were not fatal, but it seemed likely enough, from the symptoms in life, that there was in them affection of the hypoglossal nuclei among others, as there was in Dr. Barlow's case. The nervous symptoms appeared in one of them at least as soon as the eruption, and so made the term sequela a little inexact, as perhaps it would have been if Dr. Barlow had used it, for Dr. Poore was careful to point out that the pain over the breast-bone, which might be considered perhaps as a symptom of dorsal myelitis, appeared at least as early as the preliminary *malaise* of measles, and that the myelitis was at least concurrent and not consequent. Similarly in a case of Dr. Whipham's, a muscular ataxy, which was mistaken for drunkenness, was noticeable just before the eruption of variola was plain. A case which Dr. Cheadle mentioned (at present in the Great Ormond Street Hospital) of cerebro-spinal meningitis, immediately consequent on measles, was very much to the point, though, perhaps, it may be as well to remember Dr. Wilks's warning that some meningitis, even under such conditions, may be tubercular. Dr. Ormerod showed the variety of forms which the nervous symptoms take by relating three cases in the same family in which measles had been followed, after a clear interval, by a form of infantile paralysis with some points of resemblance to what Prof. Charcot and Dr. P. Miear have described in the *Revue de Médicine*, Feb., 1886, under the title of "A Special Form of Progressive Muscular Atrophy." In the French essay the tendency of the disease to run in a family is especially enforced, and Dr. Barlow was able to call to mind a similar condition.

The discussion on the whole showed a wide-felt interest in the subject, and a disposition to fill up some of the large gaps that are still left in our knowledge.

Dental Anæsthesia; Cocaine.

The Paris correspondent of the *London Lancet* says:

"M. Georges Vian claims to have solved the problem of local anæsthesia in dentistry. After numerous trials of solutions of different strengths, he has found that the soft parts about the maxillæ may be rendered completely insensible by the use of cocaine, associated with a two per cent. solution of carbolic acid. Five minutes before operating M. Vian dissolves five centigrammes (one grain) of hydrochlorate of cocaine in fifty centigrammes (ten drops) of the solution, and injects it into the gums, half-way between the neck and the extremity of the root of the tooth. Half of the solution is injected on the palatine and the remainder on the labial side, pressure being made by the finger, when the needle is withdrawn, to prevent the exit of the fluid. Anæsthesia is perfect in three minutes. The quantity of cocaine advised by M. Vian seems somewhat large, but it is said to have been so used in eighty-seven cases without causing any unpleasant symptoms. *Apropos* of cocaine, the *Semaine Médicale* gives some particulars of the fatal accident which led to the suicide of Professor Kolomnine. The professor had decided to perform an operation for the removal of tubercle from the rectum of a female patient, and inquired of his colleague, M. Louschinsky, what dose of cocaine he might administer. The answer was that the maximum was two grains. Upon consulting special treatises, however, M. Kolomnine found that thirty cases of anæsthesia were recorded in which the quantity given had varied between six and ninety-six grains. In a similar operation to that he proposed to perform, a French surgeon had given forty-eight grains. In consequence of these references it was decided to employ twenty-four grains, which were introduced into the rectum by instalments. About half an hour after the operation the first symptoms of poisoning appeared, and notwithstanding the administration of nitrite of amyl, hypodermic injections of ether, oxygen, and artificial respiration, etc., the patient succumbed. Hypodermic injections of morphia do not seem to have been tried, and I do not know whether they have been recommended in cases absolutely similar to this. I may mention, however, that I have seen symptoms of cocaine poisoning in subjects of morphia habit removed instantly by a hypodermic injection of morphia, and in one case five grains of cocaine had been taken hypodermically within ten minutes, and I have frequently seen the same antagonistic effect produced by a small quantity of cocaine in an overdose of morphia. It is also regretable that strychnia was not tried in this case, for the experiments of Dr. Bignon having shown that cocaine is its physiological antidote, it is quite possible that the antagonism may be reciprocal. Dogs poisoned by strychnia to the extent of one milligramme (a fiftieth of a grain) per pound can always be saved by keeping up cocaine intoxication until the elimination of the strychnia."

Unique Case of Dislocation of the Ribs.

Dr. Fifield reported the following case to the Boston Society for Medical Observation:

A boy about eight years old, standing near a peddler's wagon, was thrown down by some children underneath the hind wheels of the wagon, the horse started forward, and the wagon wheel went over the child's chest; over the left chest in front. Perhaps half an hour after this I saw him. There was then a dislocation of some three of the ribs (I don't remember the exact ribs) near the region of the heart; a dislocation forwards, the cartilages of the ribs lying behind, the ribs projecting in front. The child was described as having been very blue, livid, and gasping for breath, shortly after the accident. When I saw him he was breathing with considerable ease, but upon any attempt being made to push the ribs backward into their places, he again grew livid, and respiration threatening to cease, I was obliged to desist from my endeavors. I think I tried twice in this way, and on each occasion the interference with respiration made me let him alone.

There was obviously no way of placing the cartilages in any position, except by cutting a hole, and putting the hand in. I advised to have him left entirely alone, hoping that this would restore the position. The following day the projection of the ribs was not so noticeable, and within three days the projection had almost entirely disappeared, and the cartilages had resumed very nearly their natural place. Upon consulting all the works on surgery in my library, I could find no allusion to this accident, except in one of the volumes of external pathology by Barnes, and some person associated with

him. In that work it speaks of the dislocation of the ribs forward, the cartilages being placed behind. It states that there is no well anthenticated case on record. But one case is cited, and it is cited with expressions of disbelief in the occurrence of the accident, and the narrator is thought either to have drawn upon his fancy, or that the case was so ill-observed that it was unworthy of any notice. I certainly have not ever seen it in the best works of English surgery. I find not the slightest allusion to any such accident.

The Alkaloids of Jaborandi Leaves.

Professor Harnack, of Halle, and H. Meyer, in some previous publication (*Annalen der Chemie*, vol. cciv., p. 67), pointed out that pilocarpine could easily be changed into jaborine, a substance acting like atropine, and Merck even claimed that jaborine was always present in minute quantities in the commercial pilocarpine. And still another alkaloid besides pilocarpine and jaborine has recently heen obtained by Meyer, which he termed pilocarpidine, and described in the *Archiv für experimentelle Pathologie*, 1886, vol. xx., Nos. 5 and 6. Omitting the chemical properties of the new alkaloid, which approximate those of pilocarpine closely, a writer in the *Therapeutic Gazette* briefly reviews its principal physiological features as follows: The action of pilocarpidine is essentially identical with that of pilocarpine, only less pronounced. In a cat seven weeks old, which received 0.01 gramme of pilocarpidine hypodermically, the drug induced a state of intoxication, which would have been fatal unless speedily counteracted by atropine. Among the more prominent symptoms of the poisoning by pilocarpidine, Meyer mentions increased perspiration and lacrymation, besides diarrhœa, vomiting, and dyspnœa. In rabbits pilocarpidine causes likewise salivation and diarrhœa, but does not, even in doses of 0.2 gramme (3 grains), susceptibly influence the respiratory and cardiac functions. While 0.1 gramme of pilocarpine (1½ grains) produces in a rabbit a profound intoxication and death, Meyer observed, after the subcutaneous employment of 0.5 gramme (7 grains) of pilocarpidine, no materially morbid symptoms; even 0.3 gramme (4½ grains) introduced directly into the circulation caused no intoxication. It is probable that the innocuousness of the drug results from its rapid decomposition in the animal organism. In frogs pilocarpidine showed likewise a much weaker action than pilocarpine. Jaboridine (an alkaloid into which pilocarpidine is easily changed) has hitherto, by Meyer, been tested exclusively on the frog's heart, and was found to closely resemble in its physiological properties those of jaborine and atropine, as intimated above.

The Influence of Cascara Sagrada on the Digestive Secretions.

The virtues which were discovered in cascara sagrada, through the empirical use of the drug, were so pronounced as to attract to it the attention of the physiological experimenters; and although nothing new has been recently advanced, the evidence that the original claims for this tonic laxative were well founded is rapidly accumulating. Dr. Tschelzen, who has studied cascara sagrada experimentally, has arrived at the following conclusions, which he publishes in the *Journal de Médecine de Paris*:

1. Cascara sagrada is efficacious when a prompt cathartic action is looked for.

2. It acts as a purgative only after it has been introduced into the stomach; when injected into the skin or into the vessels, it does not cause an intestinal evacuation.

3. It does not increase the salivary secretion.

4. It causes an increase of the secretion of the gastric juice which is often contined during the process of digestion; it increases also the biliary and pancreatic secretions.

All these effects have been obtained when the remedy has been introduced into the stomach.

When it is injected into the vessels, animals undergo partial and often fatal collapse. The blood-pressure is rapidly decreased, even after partial dissection of the pneumogastric.

Dr. Thompson has employed the extract of cascara in more than 300 cases, administering a dose of 5 centigrams combined with 10 centigrams of berberis aquifolium, in pill form, in the morning and evening, against habitual constipation. The remedy preserves its activity even when its use is continued through several months.

Dr. Landousk has stated that the laxative effect of the powder of the bark can be obtained with a dose of 25 centigrams, and permanent effects are obtained when this dose is given three or four times a day for a few months.

The Treatment of Chorea by Cimicifuga.

The *Boston M. and S. Jour.* says:

According to Stillé, Physick, of Pennsylvania, was the first to prescribe the black

snake root in chorea. This was as early as 1821. Cimicifuga racemosa was again brought to the notice of the profession as a a remedy for chorea by Dr. Jesse Young, in the *American Journal of Medical Sciences*, September, 1832. Dr. Young prescribed the powdered root in teaspoonful doses three times a day. It was subsequently recommended by Lindsley, Kirkbride, and Eberle.

Stillé considers the utility of cimicifuga in chorea as unquestionable, and in summing up his observations on the remedy, remarks that "the cases most adapted for its use are those in which the nervous derangement is independent of any definite disease in other parts of the body. It must be used in doses of sufficient strength to develop its specific effects, particularly vertigo and confusion of sight."

Dr. Hiram Corson, a veteran Pennsylvania physician, has again called attention in the MEDICAL AND SURGICAL REPORTER to the remedial virtues of cimicifuga in chorea. He affirms that he has used cimicifuga racemosa in every case which has come to him in more than fifty years, "and always successfully in a brief time." He recommends the fluid extract of the dried root in teaspoonful doses after each meal, and a fourth dose at bed-time. Several cases reported by Dr. Corson were all speedily alleviated by the cimicifuga, and in one or two instances the duration of the disease would seem to have been materially abridged.

Dr. Corson is persuaded that none of the other remedies in general use for chorea, not excepting arsenic, have half the value of black snake-root. Its effect is, he thinks, that of a "quieter of the general nervous system," and he has found it in half-teaspoonful doses of the fluid extract a charming remedy for insomnia.

Ringer and Phillips regard cimicifuga as an excellent tonic of the nervous system, and especially suitable for cases characterized by failure of coördination.

Fungus of the Conjunctiva.

At a recent meeting of the Caucasian Medical Society, Dr. Nikolai M. Larïonoff, of the Tiflis Military Hospital, demonstrated (*Proceedings of the Caucasian Medical Society*, No. 21, 1886,) a patient, in whom, about two weeks before, there had appeared fungus of the palpebral conjunctiva, and, two or three days later, also of the tongue, buccal cavity, fauces, and urethra (near the external orifice). The general health of the man was at first quite satisfactory, but subsequently, when the oïdium albicans affected his mouth and fauces, he commenced to lose flesh, since he could not eat in consequence of painful swallowing. This is the third case of conjunctival fungus which has come under the author's observation within the last five years. Only one of the patients was in bad general health (weakened by chronic pneumonia). In all, the fungus appeared within a short time, in the buccal cavity and fauces. In one (in the weak one) it developed also on the glans penis. Dr. Larionoff is surprised to find that none of the text-books contain any mention of the disease in question. His surprise is the more justifiable, as fungus of the conjunctiva belongs to severe ocular affections leading to cicatricial degeneration of the ophthalmic mucous membrane, with subsequent lesion of the cornea. Dr. Mikhail J. Reich, of Tiflis, has also met several cases of that rare disease in debilitated adult subjects confined in prison, and in weak children imprisoned in reformatory schools. He never saw, however, any spreading of the fungus from the conjunctiva to the mouth or urethra.

Vomiting During Pregnancy Cured by Artificial Alimentation.

Dr. Brünniche, in the *Nordiskt Mediciniskt Archiv.*, relates the case of a woman who was in the hospital for two months with cardialgic symptoms. She had pain, particularly in the left side of the epigastrium, which was diminished by pressure. She could retain no food, not even milk, and sometimes vomited blood. Urine normal; no fever; temperature 37°. She was treated for a time for gastric ulcer. No symptoms of pregnancy could be found by external examination. The patient became greatly emaciated, vomited everything, and was greatly reduced after sixteen days. Strong suspicions of pregnancy were now entertained, and Dr. Brünniche determined to try artificial alimentation. A sound was introduced into the upper part of the œsophagus and milk poured through it. Other nourishment was also administered in the same manner. An attempt to dispense with the sound brought on another attack of vomiting. Artificial alimentation was therefore continued for three weeks. At the end of this time the woman had entered on her fourth month; she began to take food, and entirely recovered. Dr. Brünniche remarks that he got the idea from the treatise of Dr. E. Bull.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

EFFECT OF CURARE AND STRYCHNINE ON THE PERCENTAGE OF GLYKOGEN IN LIVER AND MUSCLES.

It is a well-known fact that diseases in which sugar appears in the blood have a peculiar influence on the muscles. Persons suffering with diabetes mellitus, though apparently becoming stronger by increasing their weight through the accumulation of adipose tissue, always experience a decided weakness in the muscles. It was thought that the presence of sugar had the influence. To determine the question, Dr. Demant (*Ztsch. f. Physiol. Chemie.*, Bd. x., H. 6,) instituted a series of experiments which led to the following deductions:

Strychnine in toxic doses rapidly produces a total disappearance of the glykogen in the liver and in the muscles. Similar, also, is the action of smaller doses not producing tetanus.

Curare, developing a state of complete rest in the motor system, being, therefore, the opposite in action to strychnine, also leads to a rapid diminution of liver- and muscle-glykogen, when administered in toxic doses. Neither the decrease in temperature, which the animals experimented upon always experience under the influence of curare, nor the dyspnœa caused by the latter, could explain its action, as artificial respiration and sustaining the bodily temperature by special means had no effect whatever. Another interesting phenomenon accompanies the poisonous action of curare; all the animals which were brought under its influence were attacked by diabetes. Curare, as is well known, also produces retardation in the lymph current, and according to Schiff, this gives rise to the formation of a ferment which separates the glykogen into its elementary constituents.

INFLUENCE OF MENSTRUATION ON THE PULSE.

According as the vis a tergo changes in unison with our position, the pulse-rate varies, whether we sit, stand, or lie down. Such at least is the case in health. The knowledge of this fact is of practical value in the examination for life insurance. Any emotion, especially in nervous persons, will at once increase the frequency of the pulse, and to determine whether in a candidate for life insurance the frequency of the pulse is due to a transient cause or to disease, all that the physician has to do is to let the applicant lie down for a few minutes, when the pulse will at once become slower and assume its normal rate, provided there is no lesion of any

kind producing the increased frequency, for then the pulse will remain the same as when standing. Hypertrophy of the heart induces greater rapidity, *not* influenced by position.

An interesting observation referring to this point has recently been made by Dr. F. Louge (*Gaz. des Hop.*, 1886, No. 147). He found that women, while menstruating, all have a pulse more frequent than usual, and no position, whether they lie, sit upright, stand, or walk, seems to exert the least influence on the pulse-rate. According to L. this is due to the altered blood-pressure always present during the menses.

ICHTHYOL.

That there really is some decided virtue in ichthyol has now been proved by extensive observations, which were made in the Charité Hospital at Berlin.

The remedy exerted a great influence in all forms of rheumatism, lumbago, gout, neuralgias, contusions, hemorrhages, burns, in case of pityriasis, seborrhœa, ichthyosis, eczema, lichen, prurigo, pruritus, herpes, acne rosacea, psoriasis, erysipelas, furunculosis, lymphangitis, panaritium, lepra, and also in some acute exanthemata. It acts as a disinfectant, contracts the vessels, and is astringent and drying, and may be used without danger for a long time externally and internally. As a rule, ten to fifty per cent. solutions or salves are employed; also ichthyol wadding, plaster, soap; internally capsules containing ten per cent. solutions of the remedy in ether, alcohol, glycerine, or water, and about eight to fifteen drops; or pills.

The remedy can now be obtained here in its pure state and at a reasonable price, and should be tried to determine whether it will act here as well as in Europe, though one observer remarked some time since that under certain climatic influences the remedy did not act so well. Probably it was adulterated.

INTESTINAL LESIONS PRODUCED BY DRASTICS.

From experiments which Dr. L. Butte made with colchicin, veratrin, croton oil, and colocynths on dogs, he has come to the conclusion that these substances, though they all lead to enteritic and ulcerative processes, each has certain characteristics of its own, which if known may be of value in forensic medicine. Colchicin causes active and extensive hyperæmia of the intestinal mucosa, veratrin acts less energetically, and its influence is limited to the duodenum and the upper part of the jejunum; the ulcerations produced by colchicin are small and round, those of veratrin larger and not so sharply rounded. Croton oil induces a dark redness in the intestinal mucous membrane; the submucous tissue is covered with wide, black ecchymoses, but the large intestine remains intact. Colocynth produces a moderate congestion, and small and superficial ulcers, while the large bowel becomes intensely inflamed.

Uræmia and dysentery develop conditions very similar, and it is, therefore, doubtful whether B.'s observations alone have any forensic value.

Notes and Comments.

Renal Irritation from Pure Terebene.

A correspondent writes to the *Brit. Med. Jour.* to ask his professional brethren whether they have ever noticed severe nephralgia and other evidences of renal irritation follow the use of "pure terebene." He has lately had under his care a case of bronchiectasis, in which he tried all the stock remedies, such as creasote, eucalyptol, iodine, phenol, iodoform, tar, sandalwood oil, and lastly "pure terebene," to try and diminish the secretion and lessen the almost gangrenous odor of the sputa. He thinks he may safely say that they all practically failed to accomplish what he intended, even though the doses were pushed. "Pure terebene" was the last experimented with, and when the patient was taking from 20 to 25 minims four or five times during the twenty-four hours, he suddenly developed most intense nephralgia, the urine became scanty, high-colored, and distinctly albuminous. There had been traces of albumen before, but it was distinctly increased at this. There was no reason to suspect renal "colic" due to other causes. After the lapse of three weeks "pure terebene" was again begun to be taken, and as the doses were increased to the same quantity as before, a repetition of the nephralgic symptoms occurred, but less marked than before, and gradually a tolerance was established.

On a New Method of Performing Excision of the Knee-Joint.

Mr. H. Allingham read a paper on a new method of performing excision of the knee-joint, before the Medical Society of London. The joint was opened by a long vertical in-

cision, and the patella divided into two lateral halves, which, together with the soft parts, were slipped to the sides of the joint; the crucial ligaments having been divided, the joint was firmly flexed, and a slice removed first from the femur, and then from the tibia; the lateral ligaments were not divided. The whole surface of the joint, and the synovial pouches, were then cleared of synovial membrane; the patella, if only slightly diseased, was scraped, and the two halves brought together and sutured; if much diseased, it could be shelled out of the entire quadriceps tendon without destroying the connection of the muscle with the ligamentum patellæ, and the split tendonous expansion, together with the split ligamentum patellæ, could be brought together with catgut sutures. Drainage-tubes were inserted through suitable posterior counter-openings, and the wound closed with separate sutures. The operation must be performed with antiseptic precautions. Mr. Allingham claimed that by this procedure the joint was more thoroughly opened to inspection at the operation; that dislocation of the tibia backwards after the operation was prevented; that the undivided quadriceps antagonized the hamstrings; that progression was better for the same reason, and that the prospect of obtaining movement was greater.

Sounding Pregnant Uterus.

Before the St. Louis Medical Society, Dr. Hulbert related an instance to illustrate the immense amount of abuse a pregnant uterus may stand. A woman was admitted to the Female Hospital with uterine trouble, who, amongst other things, had been subjected to the introduction of the uterine sound. She was insane, her delusion being that she was extremely filthy. Her husband declared that she could not be pregnant. An examination disclosed a large bilateral laceration of the cervix. After waiting one month the doctor was satisfied that she was not pregnant, and with a hope that a cure of the lacerated cervix might cure her insanity, he operated, denuding freely, and passing a sound several times into the uterus. He introduced ten sutures. In ten days he removed the sutures, finding a very satisfactory union. In eight days more, the eighteenth after the operation, the patient aborted, and was safely delivered of a fœtus of three months.

Resection of Lung and Removal of a Kidney.

M. Demons read an interesting note at a recent meeting of the Paris Surgical Society. An adult was stabbed between the ninth and tenth rib. A portion of the lung-tissue protruded, and formed a mass about as large as an apple; the same day the patient passed blood with his urine, indicating a wound of the kidney. M. Demons resected, by means of the écraseur, the hernial portion of lung, and applied the thermo-cautery to the surface. Some days after the operation, there was purulent effusion on the left side of the thorax; chemical analysis of the fluid proved it to be principally urine. It was decided to remove the kidney. Nephrectomy was performed in the lumbar region; the twelfth rib made the operation more difficult; but M. Demons, remembering M. le Dentu's opinions, carefully avoided cutting it. The pedicle of the kidney was divided, and carefully ligated. The wound was sutured with metallic threads; reunion took place by first intention, but two months subsequently a mass of cellular tissue sloughed away and opened the cicatrix. It is now six months since the operation was performed, and recovery appears to be perfectly established.

The Purity of Mid-Atlantic Air.

In the course of an address on the Action of Micro-Organisms on Surgical Wounds, Professor F. S. Dennis, of New York, states that during his last trip across the Atlantic he made some experiments to test the purity of the air about 1000 miles from land. He employed capsules of sterilized gelatine, and exposed them for fifteen minutes. One capsule was exposed in the state-room upon the main deck of the steamer. Within eighteen hours over 500 points of infection had developed. Two capsules exposed in a similar manner in a cabin on the promenade deck, where the circulation of air was free, showed five or six points of infection each ten days afterwards. A capsule exposed over the bow of the ship was found to be entirely uncontaminated. These experiments are on the same lines as those of Pasteur and Tyndall upon the mountain air of Switzerland, and, so far as they go, they show the germless condition of mid-oceanic air, and also the need for much more efficient ventilation in the state rooms of even the first-class American liners.

Borax and Epilepsy.

In the *Med. Age* Dr. C. T. Wilbur says: A boy, about 14 years of age, was brought to me March 2, 1886, for treatment, who had, for about two weeks after coming to me,

from one to six convulsions each day. I then put him on about fifteen grains of borax, three times a day. Have kept it up constantly in the same dose after each meal, and he has not had a single convulsion since —a period of a little over six months. With a liberal diet the same boy has gained thirty pounds.

Another lad, of the same age, apparently from the use of the same remedy, has had but one attack of convulsions, and that resulted, in my judgment, from an attack of a malarial fever, which yielded readily to quinine.

Other cases of epilepsy in my care, I confess, have not yielded to its use.

I only wish to express my opinion that it appears to be of value in some cases.

Poisoning by Cocaine.

Mr. Kilham related before an English medical society the case of a male, aged 30, who took 4⅘ grains of hydrochlorate of cocaine. In twenty minutes he was seized with a severe pain in the stomach and throbbing in the head, loss of sight and of power in the legs, with incoherence of speech and confusion of ideas. Severe vomiting followed, with cramps in the stomach and legs, very profuse perspiration, intermittent action of the heart, cyanosis of the face, and a feeling of suffocation; then ensued severe prostration, shiverlng, and coldness of the skin, which passed off in about three hours, but prostration and vomiting lasted all the next day. Thirty-six hours after taking the cocaine he began to lose taste, and had a leathery feeling in the mouth, and tingling of the fingers. The treatment consisted in emetics and stimulants.

Lanolin Mercurial Ointment.

Dr. Bernard Brandis, of Aachen, in his work "Principles of the Treatment of Syphilis," writes thus: "I must also mention the mercurial ointment brought forward by Professor O. Liebreich, of which the basis is formed by lanolin. This salve is thus prepared: 100 parts of mercury, 25 of lanolin, and 5 of (grey) mercurial ointment, are rubbed together thoroughly, and then mixed with 50 parts of mutton suet, to which, when melted, 175 parts of lanolin have been previously added. An elegant and smooth preparation results, without any disagreeable odor, and the trials of it here detailed speak most decidedly in its favor. Those who use it on patients boast of the ease with which it is 'rubbed dry,' and we may presume that the mercury is rapidly taken up by the skin."

Cotoine in Diarrhœa.

In the Therapeutic Society, July 21, M. Huchard read a note on the therapeutic properties of cotoine, or the extract of coto, a plant found in Bolivia. It is exhibited in the dose of two to three grains for adults in various forms of diarrhœa. It may be given in powder, in the form of an alcoholic extract or as a tincture. The wine of coto may also be made by macerating for six days an ounce of coto bark in a liter of Malaga wine.

M. Huchard gives the coto in powder, preferably in doses of three grains, with markedly favorable results in tuberculous and various other forms of diarrhœa.

The Abuse of Milk Diet.

M. Debove showed a case the other day at a Paris medical society which demonstrated the possibility of pushing a milk diet too far. The man was of very intemperate habits, and had gastric ulceration, for which he was put on a milk diet in a country hospital. At first he took only about two quarts a day, but this quantity was gradually raised to eight quarts. He became greatly emaciated, and was found to have a stomach enormously dilated. The milk was reduced to three pints, and powdered meat added, the stomach being washed out every day. Under this he rapidly improved, scarcely any splashing sound being audible over the epigastrium after meals.

Thuya Occidentalis for Warts.

"Thuya occidentalis" (arbor vitæ) is credited (says the *Medical World*) with the remarkable property of causing the disappearance, in a very short time, of all kinds of vegetations and warty growths, by its internal administration. Many successful cases are reported by French physicians; in fact, it is said to seldom or never fail. It is given in the form of tincture, from ʒss to ʒj two or three times a day. Its action is regarded as quite phenomenal in this direction. Among others, Dr. Constantin Paul reports the cure, within fourteen days, of non-syphilitic warts which covered the genitalia of a woman. It is said to be equally serviceable in the case of condylomata and other similar growths.

Iodoform in Chronic Uterine Catarrh.

Dr. Kugelmann, of Hanover, relates his experience with iodoform, which he was induced to try by its good effects on a nasal and laryngeal catarrh in his own person. His method of application of the drug is by insufflation with a metallic catheter, with lateral openings near its beak, by which the powder is taken up, and, being inserted within the uterus, it is expelled by compressing an elastic ball at the other end. The applications are made twice a week. The method is painless and free from danger, and has been very successful in the author's hands. Previous dilatations by laminaria or other tents, or by metallic dilators, may be necessary.

Absence of Knee Phenomenon in Health.

At a meeting of the Société de Biologie, April 10, 1886, Déjérine reported the case of a tuberculous patient who during life presented absence of the patellar tendon reflex. He never presented any other symptom of locomotor ataxia, no lightning pains, no ocular symptoms, no incoördination, etc. At the autopsy, the spinal cord, which was examined with the greatest care, as also the peripheral nerves, were found to be absolutely normal. This case proves that the patellar reflex may be absent, without any other symptoms or any characteristic lesion of locomotor ataxia being present.

Hydrofluoric Acid in Therapeutics.

In a remarkable thesis on this new subject, Chevy concludes that the vapors of hydrofluoric acid can be inhaled without inconvenience when diluted with air in the proportion of 1 : 1500. It is an antiseptic and a powerful anti-ferment, stopping the fermentation of milk, urine, bouillon, and preserving meat in the proportion of 1 : 3000. Its employment in pulmonary tuberculosis, diphtheria, and as a dressing for bad wounds, has yielded results worthy of further study. Great care should be exercised in its use in asthmatic, hemorrhagic, or emphysematous subjects.

Shortening the Round Ligaments of the Uterus.

Dr. P. Sabil publishes in the *Journal de Médecine du Bordeaux* some very precise directions for finding the round ligaments of the uterus for the purpose of shortening them in cases of prolapsus. He and M. Ricord have made a large number of trials on the dead body, and they have arrived at the conclusion that the Alexander-Adams operation as modified by them will probably prove a valuable means of treating cases of this kind, so as in confirmed cases to supersede the constant wearing of pessaries.

Whooping Cough.

The editor of the *Provincial Medical Journal* reports the following: "We had nine children suffering from pertussis in the Nursery, Halifax Union; we connected a piece of gas tubing with the gas burner, and turned the gas on, and each child was brought sufficiently near so that the gas might be inhaled. We repeated this for some days, and can report most favorably on the results. The intensity of the paroxysms was diminished, and the duration of the disease cut short. The infants recovered without any complications.

To Abort a Felon.

Dr. Edward T. Williams thus writes to the *Boston Med. and Surg. Jour.:*

"Some one asked how to abort a felon. I will tell him how I have aborted a great many, though, of course, this cannot be done except in the earliest stage. Tie a rag loosely around the finger and keep it constantly wet with cold water. It cures often; but probably some more fantastic appliance will better please most patients, and give them a higher opinion of the surgeon's skill."

Infantile Constipation.

Dr. Louis (*Med. Bulletin*) recommends:

℞.	Mannæ opt.,	℥j.
	Magnesii carb.,	℥j.
	Ext. sennæ fl.,	℥iij.
	Syr: zingiberi,	℥j.
	Aquæ,	℥iij.

M. Sig.—One teaspoonful two or three times daily.

℞.	Resinæ podophylli,	gr. ½.
	Spts. vini rect.	♏xv.
	Syrup,	℥j.

M. Sig.—One teaspoonful at bedtime.

Opium in Maniacal Excitement.

Before an English medical society, Mr. B. Walker related a case of an old lady, aged 84, who became so violent that the assistance of three persons was needed to keep her in bed, and preparations for removal to an asylum were made. Eleven hours' sleep followed the administration of one grain of opium. The patient's mind was restored.

Iodol in Gynecological Practice.

Dr. Ménière has used iodol with good results in cases of granular degeneration and erosion of the cervix. He uses a solution containing: iodol, 1 part; glycerin, 15 parts; alcohol, 30 parts. He has also used the solution with equally favorable results in a few cases of muciparous inflammation of the vulva in young lymphatic subjects.

Dialysate of Jaborandi.

It is often noted that we are denied the good effects to be derived from the use of jaborandi or pilocarpine because they produce a nausea that interdicts their use. Dr. Bruen recently told the Philadelphia County Medical Society that the nausea was not produced when dialysate of jaborandi was used.

Pills for Amenorrhœa.

Dr. N. Gueneau de Mussy recommends the following formula:

℞.	Salicin,	1 (grs. xv).
	Pulv. rhei,	0.50 (grs. viiss).
	Confect. rosæ,	q. s.
M.	Ft. pill No. x.	Sig.—One to three daily.

Gastralgia.

℞.	Tinct. stramonii,	℥ ss.
	Tinct. hydrastis,	℥ iv.
	Aqua laurorcerasi,	℥ ijss.

M. Sig.—One teaspoonful in water every four hours.

News and Miscellany.

As Others See Us.

To the *Boston M. and S. Jour.* we are indebted for the following extract:

An entertaining writer in *London Truth* discourses about the "Physician Himself" from the lay point of view. He says: "The easy-going general practitioner, whether in town or country, but especially in the country, has always appeared to me to have a delightful time of it. An income of some £500 to £700 a year, plenty of moving about, plenty of intercourse with all sorts and conditions of men, and the satisfaction of doing a certain amount of good, and (all things considered) not much mischief, and being paid for both—these are the charms of country doctoring. I confess, I like doctors. They are, for the most part, chatty, pleasant, tolerant men, easy to get on with. The fact is, it is their business to make themselves agreeable, and they get into the habit of being so, even with people who are not, and have no intention of becoming their patients.

"Of course, now and then a doctor may find it pay to go in for being habitually rude, and a curmudgeon. Some people—women, I think, more frequently than men—rather like a bear for a doctor. But there is this to be remembered about bearishness: it wants some sort of a reputation to back it. "Rough and Ready" are nags that sometimes go well enough in the medical tandem. But Ready must always go first. A doctor must show himself expert in his business before he sets up to be impertinent out of it. Nobody will put up with impertinence in a young man just starting, and with his spurs yet to win; nobody, that is to say, except the very poor. The very poor and ignorant, I think, like their doctor to be unpleasant, just as they like the medicine to be nasty, and do not believe in it unless it is hard to swallow. When the draught is so horrible that it seems to curdle the soul, then only do they conceive that it "is taking hold," as they say, and will do them good. But although the poor may like the physic to be bitter, and the doctor domineering and rough, these are not the tastes, as a general rule, of the more profitable class of patients. Accordingly, the doctor who means to get on makes it his business to be bland himself, and sees that his prescriptions are as little offensive as the combined resources of chemistry and confectionery will allow.

"A doctor may very easily make a fair reputation and a good deal of money without much knowledge of medicine; for this reason, that the science of medicine is a closed book to the vulgar. When a man dies, none of his friends (unless there chance to be a coroner's inquest) know in the least degree what killed him. And if you call in some great medical gun at the last moment, the great medical gun is sure (indeed, I believe by the etiquette of the profession he is bound) to tell you that your doctor has 'treated the case most judiciously.' On the other hand, when a sick man gets well, no one knows what cured him, and the doctor —who was, perhaps, on the wrong track throughout—gets all the credit. Thus, the best—indeed, almost the only—way in which a doctor can convince his patients that he is wise and knowing in his profession, is by showing them that he is a clever and well-informed man out of his profession. Of his science as a doctor they are not in a position to judge; but, if he talks sensibly about subjects which they do understand—stocks, and shares, and pictures, and last night's debate in Parliament—and has fair luck with his

cases, then his patients will trust and swear by him. I remember one very sad illustration of the injury which a doctor does himself who drops behind in his general information. A friend of mine who had married a wife from the county Westmeath (in those days a very 'disturbed' district) came home one afternoon from the stock exchange and found the lady in a terrible state of excitement, piling the fire with pill boxes, and throwing 'the mixture as before' out of the window. On investigation, it turned out that the doctor had called, and in the course of conversation had innocently and casually inquired: 'What is this habeas corpus, can you tell me, Mrs. Blank, which they talk of suspending in Ireland?' To a lady who had grown up from childhood with the habeas corpus perpetually suspended over her like a drawn sword, the ignorance thus displayed was too shocking. Not a drop of that man's medicines, she declared vehemently, should ever pour down the throats of her children. This shows, I think, that the sensible doctor will do well to look into a book occasionally, and to read the morning papers—but, of course, not the leading articles. This is a punishment reserved exclusively for the editor."

The Centennial Anniversary of the College of Physicians of Philadelphia.

The ceremonies attending the celebration of the Centennial birthday of the College of Physicians of Philadelphia which were held in this city in the early part of the present week, were conducted on a scale of grandeur well worthy of the memorable occasion. The ceremonies began on Monday afternoon, with a meeting at Association Hall, at which the President of the College, Dr. S. Weir Mitchell, made an address. In the evening there was a general reception in the college building, and a loan exhibition of portraits and objects of medical interest.

A meeting of the college was held at the college building at noon Tuesday, and Dr. Alfred Stillé, who has been a Fellow since 1842, made an address, giving his reminiscences. The honors of associate fellowship were conferred upon Dr. W. H. Draper, of New York, a son of the great chemist; Dr. R. Palmer Howard, of Montreal; Dr. Hunter Maguire, of Richmond, President of the Americ n Surgical Association; Dr. G. C. Shattuck, of Boston; Dr. J. C. Reeve, of Dayton, Ohio; Dr. T. Gaillard Thomas, of New York; Dr. D. W. Cheever, of Boston; Dr. J. C. Whitaker, of Cincinnati; Dr. Nicholas Senn, of Milwaukee; Dr. H. P. Bowditch, of Boston; Dr. J. C. Cameron, of Belmont Park, Montreal, President of the Medico-Chirurgical Society of Montreal, and Dr. D. W. Yandell, of Louisville. After the conferring of degrees, Dr. J. M. Da Costa made the new association an address of welcome. All the gentlemen who had been chosen for the honor were present, except Dr. Yandell, of Louisville, who wrote that he was too ill to travel.

A DINNER AT THE LEAGUE.

The celebration closed with a dinner in the assembly room of the Union League, Tuesday evening. Dr. Mitchell presided, and passed the massive silver loving cup that was presented to the college last winter by Mrs. Mitchell and Miss Conover.

Among the distinguished gentlemen out of town who were present at the dinner were: Dr. Fordyce Barker, New York; Dr. John S. Billings, United States Army; Dr. Traill Green, Professor of Chemistry at Lafayette College; Dr. W. H. Draper, New York; Dr. R. Palmer Howard, Montreal; Dr. Hunter Maguire, Richmond; Dr. G. C. Shattuck, Boston; Dr. J. C. Reeve, Dayton, Ohio; Dr. T. Gaillard Thomas, New York; Dr. D. W. Cheever, Boston; Dr. J. C. Whitaker, Cincinnati; Dr. Nicholas Senn, Milwaukee, and Dr. J. C. Cameron, Belmont Park, Montreal, President of the Medico-Chirurgical Society of Montreal.

Among the interesting articles on exhibition were the watch and cane of Dr. Benjamin Rush; a diploma of fellowship of the long ago; an original prescription of Dr. John Hunter, the father of English surgery; some curious old tickets for lectures at the University of Pennsylvania in the early days that are printed on the backs of playing cards; an engraving of the Pennsylvania Hospital when that institution was first established, with the farm about it and the cows grazing, and with the old almshouse near by; cards for admission to the hospital signed by Dr. Rush; a collection of old-fashioned lancets, and so on.

The Mutter Museum, which is said to be the finest in the country, outside of Washington, attracted a great deal of attention. Its histological, pathological, and other collections can hardly be surpassed. The museum occupies four rooms, in the upper story of the building which was recently added at a cost of between $25,000 and 30,000. The hall is completely fire-proof. One of its architectural features is a magnificent fireplace and mantel-piece, the cost of which

was paid out of a gift of $2,500 made to the institution by George W. Childs.

Dr. W. S. W. Ruschenberger, in connection with the celebration, is writing a historical paper on the college. He was elected a Fellow in 1838, and next to Dr. William Ashmead, who received his diploma in 1835, he is the oldest living Fellow of the college. The whole celebration was under the direction of a committee comprising Drs. Alfred Stillé, chairman; S. W. Gross, I. M. Hayes, S. Weir Mitchell, and J. Ewing Mears.

Surgery in Burmah.

The repugnance with which certain Oriental races regard surgical operations is well known; the extent to which it prevails in some parts of Burmah will be seen from the statement of a Bhamo correspondent of the *Pioneer*. From this it would appear that the majority of the natives prefer to die, or to live in a horribly maimed and disfigured condition, rather than submit to the knife; and many suffering from severe gunshot wounds, or fractures of their limbs necessitating amputation, have told the surgeons they preferred death to mutilation. This is not from any religious scruple, but purely from distrust and aversion to the knife. At the same time they will scar their bodies all over with the actual cautery, or wear holes into their flesh by the continual application of blistering fluids or mineral caustics. The result of these continual cauterizations, which are much used by the Suans as preventive and not remedial agents, are the formation on numbers of them of huge sores, ulcers, and warts of perfectly phenomenal dimensions. With English medicines, the correspondent observes, they become familiarized comparatively soon, and after they have seen the beneficial effects of self-evident remedies, such as febrifuges and aperients, they run to the other extreme, and demand medicines to cure burns, scars, lame legs, and missing toes and fingers. Surgical science has not proved, from the Burman's point of view, sufficiently practical in its results to convince him of its efficacy. It is related that the first surgical case which Dr. MacGregor, then civil surgeon, had in Bhamo was one of a gunshot wound through the knee. It being found impossible to save the leg, it was amputated, and healed most successfully. On recovery, the patient was provided with a wooden leg, and stumped about the bazaars paying visits to his friends, who, of course, had long ago given him up as a dead man. The sight, however, was not encouraging to the Burmans, who said they had never seen a man with only one leg. They thought that, perhaps, it was better the man's life had been saved, but at the same time, unless the English medical man could make a new leg grow in place of the missing one, he was not justified in cutting it off. A short time since, the civil surgeon had some more amputation cases in four wounded elephant drivers. They had been wounded, and were almost dead. Three of the men, the correspondent believes, died, and one made a marvellous recovery. Though snatched from the very jaws of death, all the merit of saving the man was destroyed in the eyes of the Burmans because he appeared minus a limb.

Crime and Responsibility.

Dr. Daniel Clark thus concludes a paper on this subject in the *Canada Med. and Surg. Jour*:

1. The natural history of crime shows that brains of chronic criminals deviate from the normal type, and approach those of the lower creation.

2. That many such are as impotent to restrain themselves from crime as the insane.

3. That immoral sense may be hidden from expediency, by the cunning seen even in the brutes, until evoked by circumstances.

4. No man can shake himself free from the physical surroundings in which he is encased.

5. Crime is an ethical subject of study outside of its penal relations.

6. Insanity and responsibility may coexist.

7. Some insane can make competent wills, because rational.

8. The monomaniac may be responsible should he do acts not in the line of his delusion, and which are not influenced thereby.

9. Many insane are influenced in their conduct by hopes of reward or fear of punishment in the same way as the sane; the rudiments of free-will remain.

10. Many insane have correct ideas in respect to right and wrong, both in the abstract and concrete.

11. Many insane have power to withstand being influenced even by their delusions.

Leprosy in the Sandwich Islands.

The Hawaiian Legislature has recently issued a report on leprosy. It has been said that this disease was introduced in 1828 by a Chinaman, and was hence called by the natives the Chinese disease; but it is proba-

bly much older than that. It was not until 1845 that the law was passed that all lepers should be sent to the hospital on the island of Oahu, near Honolulu. Once public attention was called to this loathsome disease, and a search instituted, it was found that there was a terrible amount of it on the islands, and every effort was made to stamp it out. The entire native population in 1882 was reckoned at about 40,000, and from 4 to 5 per cent. of this number were leprous. One great source of infection is found in the tenacity with which people cling to their leprous kin even to the last, and prefer to see them gradually drop to pieces at home rather than send them to the living death of the lepers' hospital. In the Molokai leper settlement there are about 700 patients awaiting death; and in the twenty years or its existence there have been about 3,000 miserable victims within its walls.

Leprosy in Riga.

At a meeting of the Riga Medical Society, Dr. Bergmann made a communication which proves beyond any doubt that Riga is one of the regions where leprosy is endemic. During the last twenty-one years there were admitted to the local General Hospital as many as fifty-two cases of the disease. This number may be considered large—especially in view of the fact that only such lepers were admitted as suffered from some intercurrent affection, or from open sores. In addition, Drs. Bergmann, Jansen, Bernsdorff, Carblom, and Stavenhagen, all of Riga, each saw several cases in their private practice. Of the hospital patients above mentioned, 39 were either natives or old inhabitants of the town. Twenty of them (8 men, with 2 deaths and 12 women with 3 deaths) suffered from the tubercular form of the affection; 7 (4 men and 3 women with 2 deaths) from the anæsthetic variety; 10 (7 men with 2 deaths, and 3 women) from a mixed form. For the remaining 2 (men) the type of the disease was undetermined.

The Peculiar People in Russia.

In the *Permsky Epidemiologitchesky Listok*, No. 8, 1886, p. 117, Dr. D. Nikolsky, of Shemakhinsky Zavod (on the Ural), writes that in his district there exists a religious sect called *Perevreshtchentzy* (Anabaptists), the members of which regard any medical treatment as a great sin, and accordingly keep all cases of disease occurring in their midst as far as possible secret from medical men. Every proselyte is first of all baptized anew; in other words, he is obliged to take a bath either in a river or in a big tub filled with cold water. The procedure is carried out without any regard to the proselyte's health and strength. Dr. Nikolsky saw cases in which patients suffering from typhus fever, after admission into the sect, were at once duly bathed in a river in April, and died two or three days later in consequence.

Patent Medicines in Russia.

A list of patent medicines, the importation of which the Russian Government has decided to prohibit, has recently been published. It consists of about 800 preparations of English, American, French, and German origin, the English or American numbering nearly 100. Pills, plasters, hair restorers, cough drops, medicated foods, ointments, and many miscellaneous preparations for a great variety of purposes, are all classed together in one long medical *index expurgatorius*. The list appears to have been drawn up by a committee of Russian physicians, and even such remedies as taraxacum and podophyllin have been struek out.

A Monstrosity.

The thirty-ninth number of the *Gazette Hebdomadaire des Sciences Médicales* contains two figures and descriptive text of a so-called cyclocephalic monster. The chief feature in the monster is the want of development of the nasal region, attended with the approachment of the two orbits, so that they have become partially fused. A further degree of this deformity leads to the complete fusion or want of differentiation between the two orbital regions, and there is then but one organ of vision. In the specimen in question there was a rudimentary nasal appendage, which formed a kind of flap that partially concealed the abnormal orbital region.

Health Exhibition at Warsaw.

We are informed that a Health Exhibition will take place at Warsaw in May and June, 1887. The objects exhibited will be chiefly of Polish make, but foreign goods will not be excluded. The exhibition will be under the patronage of the Countess Potocka, and the following are the officers already named:

President—Professor Szokalski, M. D.

Vice-Presidents — Professor Luczkiewicz, M. D.; M. Grotowski, Chief Engineer of the

City of Warsaw; and M. Janicki, civil engineer.

General Secretary—J. Polak, M. D.

Hearing Plants Grow.

The *National Druggist* tells us that it is now possible to hear plants growing. At a recent meeting of the Silesian Botanical Society an apparatus was shown in which the growing plant is connected with a disk, having in its centre an indicator which moves visibly, and thus, on a scale fifty times magnified, denotes the progress of growth. Disk and indicator are metal, and when brought in contact with an electric hammer, the electric current being interrupted at each of the dividing interstices of the disk, the growth of the plant is as perceptible to the ear as to the eye.

A New Bacteriological Journal.

A new *Centralblatt*, devoted to the subject of bacteriology and animal parasites, will shortly appear in Germany, under the editorship of Dr. Oscar Uhlworm, in Cassel. The extensive and rapidly increasing literature on these subjects, and the absence of any weekly journal devoted to this particular science, will render this venture acceptable to all who interest themselves in these matters. The contents of the journal will embrace references to recent work, historical essays, and original papers. Dr. Uhlworm will be assisted by a numerous staff of collaborators in the various European countries.

Training of Nurses in Japan.

Arrangements have been made to organize a school of nursing in Kyoto, Japan, under the superintendence of Dr. Berry and Miss Linda Richards, an American lady, who has had large experience, not only in New York and Boston, but in several British and Continental hospitals. The school, which is specially connected with Christian missionary effort, will give a course of training of about eighteen months' duration, including both theoretical teaching and practical work. A diploma in nursing will be awarded to those who prove themselves competent.

A Crisp Ante-mortem Statement.

A party of prospectors came on the body of a man in an out-of-the-way place. They did not recognize him. He was a stranger. He had not been shot, he had not been killed by a blow, he had not been attacked by a wild animal, he had not fallen over a precipice, he did not look as if starvation had killed him. They were speculating on the cause of death when they saw a scrap of paper pinned to his clothes. They took it off, and with some difficulty they deciphered this legend: "It was the rattlesnake. I tried to catch him by the tail."

Ginger-Bread versus Whisky.

A nice old lady has a certain test which she applies to all young men who "pay attention" to any of her granddaughters. After a certain time she offers him some of her home-made cake. If he eats it with avidity she mutely gives consent; if not, she instantly begins to oppose the match, not as some might suppose, from wounded vanity, but because she has a theory that men who like cake never drink to excess, or live dissipated lives of any sort. "Give me," she says, "the man that loves ginger-bread; it's a sure sign he isn't fond of whisky."

A Maid Not to be Stumped by a Leg.

The young men attending the Harvard Medical School have a prejudice against the female students, one of whom is Miss Annie Copeland, of Bridgewater. They called her to attend a case of fracture of the leg. The patient was a man 50 years old, and when the lady exposed the damaged member she found it to be a broken wooden leg. She sent for a hammer and nails, made substantial repairs, and charged $25, the collection of which she enforced by the aid of a constable.

Artificial Butter in Denmark.

The Minister of the Interior in Denmark has found it necessary to lay a bill before the Folkething regulating the trade in artificial butter. If this bill be carried, dealers will be compelled to pack such "butter" in cases marked "margarine." As no mention is made of any provision in the bill compelling the retailer to state to his customers that he is selling butter, it is to be feared that consumers will not benefit to any great extent.

The Influence of Climate and Soil upon Medicinal Plants.

According to Professor Vogel, plants do not always contain their characteristic alkaloids when grown under other than natural conditions. Hemlock does not yield coniine

in Scotland, and cinchona plants are nearly free from quinine when grown in hot-houses. Tannin is found in the greatest quantities in trees which have had a full supply of direct sunlight.

How would Iodoform Answer the Description?

The *National Druggist* says that one of its readers sends it the following:

Sir: I have cut my foot Bad with an ax I want you to Send me Some Powders. I have forgotten the name of it. The color of it is *yellow*, and it stinks like the *devil.* I have none of its being used on a sore ——. Any thing else that's good Send it along and oblige, —— ——.

The Milk of Rabid Cows.

The Russian newspaper *Vratch*, in announcing the establishment at Moscow of an Institution for the Preventitive Treatment of Rabies, asks whether persons who have drunk the milk of a cow suffering from rabies should be subject to preventitive inoculation. This question has arisen in connection with a family at Odessa.

Punishment of a Russian Quack.

A quack in Moscow, who was formerly a soldier, recently gave a syphilitic patient a mixture which caused vomiting and acute gastritis, which was ultimately followed by death. The quack was brought before the local court of justice, which sentenced him to two months' imprisonment and ecclesiastical penance.

The Pharmaceutical Chemists in Havana.

The pharmaceutical chemists in Havana are complaining bitterly of a new regulation of the Spanish military authorities ordering the pharmaceutical department to arrange to supply all military men and their families with medicines of all kinds at cost price.

Personal.

—As Dr. A. Jacobi has resigned from the Committee for Collective Investigation of the International Medical Congress, he requests answers to the circulars sent out to be forwarded to Dr. N. S. Davis, 85 Randolph street, Chicago, Ills.

—Dr. Robert O'Reilly, who is attending President Cleveland, was a Philadelphia boy and is well remembered in the old district of Southwark. He was a pupil—and a very lively one—at the Zane Street Grammar School, and took a partial course at the High School.

Items.

—Mrs. Keppler, the wife of Editor Keppler, of *Puck*, called in a doctor to look at a favorite cat,and subsequently received a bill for $22 for chopping off a portion of the animal's tail.

—A statue in memory of "Sister Dora" was recently dedicated at Walsall, England, the cost of it being defrayed by Miss Lonsdale, out of the profits whlch she received from her biography of her deceased friend.

—Several cases of trichinosis have occurred recently at Rupersdorf, in Germany. Two women have died from the disease, and many inhabitants of the town are seriously ill from the same cause.

—Dr. Henry Hun reports in *The American Journal of the Medical Sciences* for January, seven cases of cerebral disease, which throw some light on the obscurity which still involves the theory of cerebral localization.

—At the election held last week for officers of the Philadelphia Hospital, Dr. John B. Deaver was elected surgeon; Dr. Roberts Bartholow, neurologist; and Dr. W. H. Wallace, physician-in-chief of the Insane Department.

—Dr. T. J. Shepherd, in the January number of *The American Journal of the Medical Sciences*, reports a case of the very rare disease, ainhum, occurring in a negro, aged forty-seven, and he gives a brief general account of the affection.

—In reply to a correspondent asking for the best internal finish for a contagious ward in a hospital, the *Sanitary Engineer* answers: "The best finish for walls in such a hospital ward is probably a good sand finish, on which should be placed three coats of paint. This appears to be the least liable to cracks and scaling, and is readily cleansed and disinfected. The best floor is oak or hard-pine, oiled. A painted floor is not satisfactory."

—A remarkable increase in the number of suicides committed by German soldiers is reported. In the Prussian, Würtemberg and Saxon corps, and in a Bavarian brigade, the total number of suicides in May was twenty-three, in June twenty-five, in July twenty-two, and in August twenty-one. At the beginning of the year the number of suicides was less considerable. In the first eight months of last year, the number of suicides in the corps above mentioned was 149.

Pallas Syringe."

[From the *London Medical Record.*]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche,"
See page 8.

SOLUBLE
PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by
ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1054-1556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant. Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

NOTES ON THREE CASES OF TROPICAL BERI-BERI, AND ON SOME ANALOGOUS INDIGENOUS CASES OF MULTIPLE NEURITIS.*

BY E. C. SEGUIN, M. D.,

Of New York.

Having been courteously invited to participate in this evening's symposium on neuritis, I bring my mite of contribution in the shape of the relation of three cases of beri-beri, which, coming from tropical parts, have been under my care. That this disease is rarely seen in our latitude, though very common in South and Central America and in the islands of the Gulf, I infer from the fact that it has not, to my knowledge, been discussed in medical societies or in private relations in New York during the past ten or fifteen years.

My apology for relating the following cases is that they well illustrate the prominence of neural symptoms in beri-beri, and that they justify the opinion expressed by a number of observers (Dr. B. Scheube and others) that beri-beri, or kak-ke, as the affection is called in Japan, is essentially a multiple poly- or pan-neuritis, occurring as an endemic infectious (?) disease in many countries of the globe, in both hemispheres. That beri-beri, or kak-ke, is nothing more than a multiple neuritis, I am not prepared to say; and, indeed, my experience is so extremely limited that I can only use my cases to illustrate the probable neural origin of many of the symptoms of the disease.

In looking for notes of cases of multiple neuritis occurring in my local practice, I found several. One, very typical, was recorded under the title of alcoholic polyneuritis; others were included in my essays on poliomyelitis anterior,† as examples of that disease. These three cases were marked by the ordinary symptoms of multiple neuritis—numbness and partial anæsthesia, irregularly distributed atrophic paralysis, with degenerative reactions; and, besides, by œdema of the extremities. I was struck by the resemblance of these cases, thus symptomatized, to mild cases of the mixed form of beri-beri. There is quite a resemblance, if not a similarity, between Cases 1 and 2 of the category of beri-beri and Case 1 of the category of indigenous neuritis.

Another aspect in which a study of beri-beri is of interest to us, is that the disease may take root and acquire considerable development in the United States. It appears that the affection has prevailed in Para, Brazil, for only a few years, perhaps only since 1878, having been brought there from Southern Brazil and Paraguay; and that it is not uncommon in Cuba (at least the so-called wet form), and it may very well show itself in the Gulf States.

With this brief preface, I pass on to the cases themselves.

FIRST CATEGORY; CASES OF BERI-BERI.

Case 1. A Cuban lawyer, aged twenty-six, consulted me September 9, 1885, with letters from Drs. Landeta and Desvernines, of

* Read by invitation before the Philadelphia Neurological Society, November 22, 1886.

† Myelitis of the Anterior Horns; or, Spinal Paralysis of the Adult and Child. New York, 1877. (Private Edition, 1874.)

Havana, of which the following is an abstract: Married man of good constitution. Never had syphilis, scrofula, or paludism; never seriously ill. In summer and autumn of 1884, dyspeptic symptoms.

Symptoms of present illness: (1) Early in November, 1884, pains in lower third of both legs. (2) In a few days these parts were slightly œdematous, while the malleoli and feet remained free from swelling. (3) Simultaneously, cardiac palpitations; rapid pulse, from 110 to 120. (4) Some muscular weakness was noticed in legs: walk difficult and done on tip-toe, or on forward part of foot. (6) Toward end of November the pulse was steadily 120 or more beats; large objective palpitations and souffles were noticed over cardiac area. (7) Œdema appeared in the face, invaded the whole of the legs, thighs, feet, and genitals. (8) The muscles of the thighs and legs became soft and painful to touch; there seemed to be intra-muscular œdema. Toward the end of the month patient was unable to leave the bed; the palpitation was intense, and there was great dyspnœa. The thenar and hypothenar eminences became soft; the patient could no longer write, or use fork, spoon, etc. Later, the weakness became such that the legs could not be lifted from the bed; face was nearly twice its normal size. The patellar reflex was abolished. Some muscles showed loss of contractility under electricity (*vide infra*).

As a summary of symptoms in the fourth and fifth weeks of the disease, it may be said that there were anasarca, paralysis with electrical changes in certain muscular groups, cardiac bruits, with pulse up to 140 beats per minute, dyspnœa. At no time was there fever, and no albumen or sugar was ever found in urine.

Under the use of infusion of digitalis, cinchona, and nutritious food, these symptoms abated, and there was decided improvement by the end of December (eighth week). Under electrical treatment and sulphur-baths the motor paralysis gradually passed off, and the patient was able to stand in March; steady improvement thereafter continued; the cardiac symptoms had about ceased by the end of December.

Dr. Desvernines' letter refers more particularly to the state of the heart, and to the electrical reactions. At the height of the disease, the heart was enlarged, more especially the left ventricle, and the murmur heard was a mitral regurgitant one. These signs were due, Dr. Desvernines believes, to myo-cardial lesions; the endocardium being unaffected. This view is borne out by the disappearance of the symptoms.

There was no apparent pseudo-hypertrophy of all muscles of the body (œdema). A piece of muscle removed by Duchenne's trocar showed simple atrophy of its muscular fibrillæ with intra-muscular œdema and proliferation of the connective tissue. The electrical reactions were not taken during the acute period of the disease, but afterward were very fully studied, and there were found with both currents the "reactions of degeneration, characteristic of perverted nutrition in nerve and muscle."

The diagnosis made by Drs. Landeta and Desvernines was beri-beri or kak-ke, of the mixed form, and Dr. Desvernines recognized in the case the grounds for the views advanced by Scheube and Balz (from studies of the disease in Japan), that it is essentially a multiple neuritis. It is interesting to add that, while the wet form (anæmic œdematous type) is well known to the physicians of Cuba and Havana, not one of several who saw this case with Dr. Landeta had seen an example of the mixed form.

When I examined Señor M., about ten months after the beginning of the attack, he presented no objective symptoms except a degree of abnormal flushing of the face. Except a slight quantitative reduction in contractility of the calf muscles, I noticed no abnormality in the faradic and galvanic reactions of nerve, trunk, and muscles. The pulse was slow, from 67 to 65, and the heart normal in size and sound. The patient complained of occasional vertigo, and want of power of mental concentration. He was well about October 10.

Case 2. Mr. J. G., a married man, thirty-eight years of age, a native and resident of Panama, was brought to me, for consultation, by Dr. Pio Rengifo, of New York, on November 17, 1885. Is a tall, strongly built man, who has enjoyed good health, except that sixteen years ago he had a single chancre with suppurating buboes, but no secondary symptoms. Had a year's experience with Dupuytren's pills and iodide of potassium. A healthy child has been the result of marriage. In the past eight years occasional palpitations, supposed to be due to gastric disorder. Is temperate in use of stimulants. About two months ago noticed numbness in toes and fingers. This has continued as a constant symptom, affecting tips of fingers, toes, and forward part of soles; on lying down, however, there has been a certain sense of numbness in the legs and forearms. Pains appeared later, of two kinds: first,

aching pains in the calves, which were hard and tender; second, sharp pains in spots in fingers, legs, and feet; not, however, repeated pains in spots, with cutaneous hyperalgesia (not fulgurating pains). Knees were weak, and toes seemed cramped. Had sensation of band around toes. Had no vesical paresis, loss of sexual power, or spinal pains; no abnormal reflexes in legs, no diplopia. In last three weeks distinct œdema of feet and legs; has noticed that the calves measure two or three centimetres more in the evening than in the morning. During the past fortnight there has been marked improvement in power of legs, and in the paræsthesiæ.

Examination. — No objective symptoms about eyes or face. Grasp: right side, 38 and 32 degrees; left, 31 and 22 degrees; decidedly weak for a man of patient's muscular development and size. Sensibility is not positively diminished in fingers, but there is some confusion in estimating number of points applied; distinguishes texture of cloths well. No analgesia. Fingers are skilful; handwriting unchanged.

Lower extremities: No patellar reflex; walks a little awkwardly, with slapping of the feet; but, strictly speaking, there was no ataxia. Staggers when standing with eyes closed and feet together, but with eyes open stands fairly well, even on one foot. Sensibility to æsthesiometer is dull, but he localizes impressions well; no analgesia. Those movements of toes which are controlled by interossei are limited. There is yet a trace of œdema over the tibiæ. No electrical examination.

I concurred in Dr. Hengifo's diagnosis of beri-beri or multiple neuritis, and the same opinion was expressed by Prof. Charcot, who saw Mr. G. shortly after. I recently learned that entire recovery took place in a few months. It may be of interest to add that Mr. G. presented complete transposition of the viscera, his heart (the sounds of which were normal) being distinctly on the right of the sternum, and his liver on the left side; he was, however, right-handed originally.

Case 3. Señor J., aged fifty, a native and resident of Para, in Brazil, was referred to me by my friend, Dr. Charles E. Simmons, on November 11th, and is now under observation. Former health good; never had beri-beri or severe malarial fever. Subject to "bilious attacks." In August of present year had bleeding hemorrhoids for three weeks, followed by weakness of legs. This was soon followed by tingling numbness and pains in the legs, and lastly by œdema, not affecting feet. By advice of physicians, Mr. J. sailed from Para, October 27th, but instead of immediately improving, he grew worse. Soon noticed numbness and awkwardness of hands; the weakness and œdema of legs increased. In the last six days the long extensors and the long flexors of the right thumb have shown paresis, and in the last four days the same muscles on the left side have been affected. No dyspnœa, vertigo, or mental symptoms. No fever observed; urine high-colored. The pains were never severe.

Examination.—Stout, well-built man; complexion pale, muddy, and tanned. No motor or sensory symptoms in eyes or face. Heart normal; no effusion in pleura. Upper extremities: all voluntary movements present except extension and flexion of phalanges of both thumbs; the two long extensors on both sides are completely paralyzed, and the long flexors partially so. The thumbs hang as do fingers in certain cases of lead paralysis. The left extensor indicis is weak. The abductor pollicis longus, and the small hand muscles, are normal on both sides. Apposition well done. Supinators strong. No ataxia. Grasp: right and left, each 25 degrees on dynamometer. Sensibility is normal to æsthesiometer on finger-tips; but, by pricking, a limited area of analgesia (incomplete) is found over the left metacarpus, in the ulnar territory. Temperature well perceived. Lower extremities: the walk is somewhat feeble, but not pathological in type; can stand upon his toes, and equilibrium with eyes open or closed is nearly perfect. No ataxia. Patellar reflex subnormal on both sides. Both legs present a soft œdema in their inferior half; the calves are large but flabby. No swelling distal of ankle-joints. All voluntary movements of legs, feet, and toes can be performed; though extension and flexion of toes are done feebly. The great toes are not as much affected as are the thumbs. Sensibility is slightly dull to touch (a numb feeling) as high as the umbilicus; but the only zone of actual analgesia is on outer (fibular) side of left leg in its lower third. Temperature well perceived. Urine is dense, deposits urates; without albumen; a few small hyaline casts. Summary of electrical examination: Arms, no faradic or galvanic nerve reaction in extensor primi et secundi internodii pollicis on either side. These muscles do not respond to faradism, while galvanism yields a slow contraction, with marked tendency to tetanus: CaCC=AnCC or CaCC<AnCC. In flexor longus pollicis (both sides) there is no nerve reaction, and only a faint oscillatory C, with

a strong faradic current applied directly to muscle. Galvanism gives a slow contraction: CaCC=An CC, and the latter tending to tetanus. The long extensors of fingers on both sides yield reduced faradic contractility, and rather sluggish galvanic contraction, through CaCC> AnCC. Legs: Quantitative reduction to faradism and galvanism in calves: CaCC=AnCC. Extensor longus pollicis and extensor longus digit. have almost no faradic contractility, and to galvanism yield slow C, with CaCC=AnCC, the latter almost tetanic. Through external popliteal nerve better contractions (both by faradism and galvanism) are obtained in these muscles. Tibialis anticus and small muscles of feet, normal reactions. In other words, we have in this case a well-marked DeR, limited to the nervo-muscular apparatus of both thumbs; partial DeR in long extensors of fingers, and in extensors (and flexors) of toes.

SECOND CATEGORY: ANALOGOUS INDIGENOUS CASES.

Case 1. Mrs. X., aged forty years, seen in consultation with Dr. Carreau, of New York, in November, 1885. There is a clear history of excessive drinking and sexual indulgence for many years. Patient is still drinking brandy steadily. For more than two years has suffered from gastric catarrh and failing memory. Early in past summer felt burning sensations in feet, pains in feet and legs; occasional numbness in feet and hands. At end of July marked increase in gastric symptoms, diffused swelling of hands and feet with pricking numbness and a hyperalgesic state of same parts. Was unable to walk. No arthritis. Hands have also been weak. No bladder symptoms. Pains have ceased, but hands and feet are in state of painful formication; dreads to be touched. There is frequent vomiting of food and mucus. Partial dementia, with a few delusions. Urine examined several times; no sign of renal disease.

Examination. — Tongue tremulous and foul. No motor or sensory symptoms in eyes and face. The grasp is feeble, but long extensors and flexors all act. Opposition of thumb is impossible; marked atrophy of rrdial side of thenar eminenees. Examination shows marked reduction in tactile sensibility in tips of all fingers. The hands are œdematous, with dorsum tense. No arthritis. Lower extremities examined seated; feet puffy and tense, but not red; no arthritis. All movements of feet and toes are possible, though feebly done. State of sensibility cannot be well studied, owing to patient's absurd fear of all instruments and manipulations. This also prevents any electrical tests. Patellar reflex abolished (?). Spine not tender.

Diagnosis.—Alcoholic multiple neuritis.

Treatment by reduction of brandy, injections of strychnia, galvanism, and massage begun. Carsbad sprudelsalz for gastric catarrh. A note received from Dr. Carreau, a few days ago, states that faradism did not produce contraction at first, and galvanism was used alone until March, when both currents were employed. In March began to walk, and has steadily improved. Now well, except feebleness of memory and some numbness.

It is interesting to consider that this and other alcoholic cases bear a certain etiological relation to tropical beri-beri. In both cases we have subjects living upon a relative or actual excess of carbonaceous food, alcohol or rice, as predisposing, if not efficient causes of neuritis.

The two following cases were published in my essay on "Myelitis of the Anterior Horns" (1874 and 1877) as examples of that affection. Reading them in the light of recent advances in nerve pathology, they now appear to have been cases of multiple neuritis, with dropsical symptoms, making them strongly resemble beri-beri or kak-ke. I give them merely in epitome, referring to the original for details.

Case 2 (Case 18 of essay). Male, aged forty years, seen in January, 1874. In September severe "cold," with bronchitis, temporary suppression of urine, swelling of face and feet, lasting three or four weeks. Some stiffness and subjective coldness in feet. Relieved by strychnia. October 16, feet heavy and cold, hands awkward, and fingers numb. Increasing loss of power in legs. Physician stated positively that neither this nor the former attack was due to Bright's disease. In November marked anæsthesia and nearly complete paralysis of both legs; thigh muscles remained active; no rectal or vesical symptoms. Median distribution in both hands, anæsthetic; the hands and forearms rapidly wasted. No bedsore or cincture feeling. No cerebral symptoms. Improvement from end of December, when movement appeared in toes.

When examined by me he presented an atrophic paralysis of both hands, with partial anæsthesia (mostly tactile) of finger-ends. Toes (except great toes), feet, and legs, can be pretty well moved in bed; legs much atrophied, especially in anterior tibial group

of muscles. Feet are partly anæsthetic, but present (as do the legs) marked hyperalgesia. No faradic reaction can be had in either extensor pollicis, and only feeble contraction in thenar eminences. These muscles contract well, however, to galvanism (DeR). Complete recovery occurred by end of summer.

Case 3. (Case 19 of essay). Male, aged forty-seven years, seen in March, 1884. Large, healthy man. Severe "cold" in October, 1883, with bronchitis, slowly followed by numbness and paresis of limbs. The numbness appeared at about the same time in the ends of the upper and lower extremities. November 10, walking was possible only with the assistance of a stick or a person, but he could still dress himself. Swelling of the feet, with glossy skin, was marked; by November 14th, subjective coldness of feet. A few days later was unable to sit up in bed; much formication up to the knees, and halfway up the forearms; some anæsthesia (?) of the feet. No head or eye symptoms; bladder and rectum normal. In the middle of January, 1884, intense formication ushered in recovery; gradual improvement in power of legs and hands. Feet remained a little swollen. Some wasting of legs. In January noticed numbness in distribution of left superior maxillary nerve on face. Can now walk with help of cane and crutch.

Examination.—No facial symptoms. Movements of arms and hands good, except that extension of the right fingers is incomplete, and is very feeble on the left side, especially for the thumb and index finger. Palmar muscles emaciated, but not atrophied. Sensibility good. Grasp: Right, 26 degrees; left, 16 degrees. Co-ordinates well. In lower extremities the only paralysis is below the knees. The left foot is but slightly movable; the right, a little more. Toes are somewhat contracted in flexion. Sensibility to contact is good down to ankle, dull below that, very dull in toes. Toes are numb. No œdema of feet or legs. Urine is dense, but free from any signs of renal disease. Electrical examination shows very great loss of faradic contractility in palsied muscles, almost complete in left extensor indicis, and in extensors of toes and flexors of feet (anterior tibial groups); feeble reaction in calves. All these muscles, however, react well to galvanism (DeR).

These three indigenous cases of multiple neuritis—one clearly of alcoholic origin, the others of unknown etiology—I submit with but little comment. They were characterized by a combination of paræsthesia and anæsthesia, by paralysis with atrophy and DeR, of irregular peripheral distribution, and by œdema of the extremities, without signs of renal disease. Bronchitis occurred a short time before the nervous symptoms appeared in the two non-alcoholic cases. Cardiac and respiratory symptoms, indicating neuritis of the vagi and the phrenic nerves, were the only ones wanting to produce a symptom-group almost exactly like that of severe beri-beri or kak-ke.

Consult B. Scheube, Die Japanische Kakke (beri-beri), *Deutsches Archiv. für Klin. Medicin*, xxi., p. 141; xxii., p. 83 (1882–1883).

SUPRA-VAGINAL HYSTERECTOMY FOR FIBRO-CYST OF THE UTERUS IN A NEGRESS.*

BY WILLIAM PAWSON CHUNN, M. D.,

Of Baltimore.

Chief of Clinic to the Chair of Diseases of Women and Children, University of Maryland, Assistant Surgeon to the Woman's Hospital, etc.

Heretofore, Mr. President, in cases of abdominal surgery reported to this society, it has been my good fortune to have met with success. It seemed to me that most of these cases, in addition to a favorable termination, had points of interest which rendered them worthy of record. From the number of successful surgical operations one sees in every journal published at this period, we might be led to infer that it was rather unfashionable to publish unsuccessful cases. Such an inference one must allow is many times correct. Reports of successful operations alone may benefit the operator; reports of unsuccessful as well as successful operations is what benefits science. Certainly, as a rule, there is no more necessity for recording an operation that terminates favorably than it would be if it terminated unfavorably, for we all know that the causes of failure diligently inquired into are apt finally to eventuate in success. Bearing these facts in mind, I thought it not inappropriate to bring before the society to-night the history of a hysterectomy, which, although ending fatally, exhibited much that was instructive.

My patient was a colored woman, quite dark in color, twenty-four years of age, unmarried; no children, and no miscarriages. Menstrual periods regular (in quantity), and lasting only four days. The patient was kept under observation by my brother-in-

*Read before the Clinical Society of Maryland, October 15, 1886.

law, Dr. Robert T. Wilson, and myself, for the space of one year, during which time, by monthly examinations, we noticed a distinct and rapid increase in size of an abdominal tumor. From the size of a cocoanut it had rapidly grown as large as an adult head, and, by its presence in the pelvis, produced many grave symptoms. Her ability to gain a livelihood was rapidly decreasing, pain in the pelvis was constant, difficulty in defecation was very great, and pain and lack of power to urinate frequently resulted in retention. Examination by sound showed the uterus to be three inches in length and displaced to the left side. Bimanual examination indicated that the growth was attached to the uterus, as every motion given to the tumor imparted a like movement to the uterus, which movement could be plainly distinguished by the finger in the vagina. Abdominal palpation discovered a round solid tumor projecting two or three inches above the umbilicus. Fluctuation was always absent, except upon one occasion, when it was perceived, but so indistinctly as to leave the diagnosis unaffected. These signs all pointed to fibro-myoma of the uterus, and an opinion to that effect was given. As the Woman's Hospital was closed during the month of June last, the patient was turned over to me for treatment. Being a charity patient, she was admitted as such to the Gynæcological Ward at the University of Maryland Hospital, and came under my charge, Prof. Howard being abroad on his summer vacation. The question then presented itself, What could be done to relieve this woman of her infirmity or prevent the future increase of the growth? Here was a fibroid growth (according to the diagnosis) in a colored woman, 24 years of age, which in one year had increased from the size of a cocoanut to the size of a man's head. What would the size of that tumor be in three or four years? I judged by that time it would have been large enough to have produced a slow and lingering death, and after knowledge gained by the operation went to support that belief. After a great deal of hesitation, I decided to make an exploratory incision and see what was the proper thing to be done. As I had seen Dr. T. Gaillard Thomas take out the ovaries in just such a case, it was my intention to do that operation if possible, and then sew up the abdomen, the tumor still remaining in situ. If the ovaries could not be found after reasonable search, and if the tumor was without a pedicle, I thought the best thing to do would be to stitch up the abdominal wound, and leave the woman in her original position, as I had not the least yearning to do a hysterectomy. The patient being perfectly willing for anything that promised any means of relief, was gotten ready for operation, and put upon the table Saturday, July 10, 1886, and, being etherized, I made the usual incision in the median line, and in a very few moments was in the peritoneal cavity. Enlarging the incision with the scissors, which are infinitely superior to the knife for the purpose, I inserted two fingers, and found, after some search, both ovaries; the left moderately movable, but low down in the pelvis, while the right was rather more fixed in Douglass's pouch behind the uterus. As the pelvis was almost filled up with a vascular, reddish-looking growth, evidently uterine in character, it at once became evident that to reach the ovaries it would be necessary to enlarge the incision, and lift the tumor out of the abdominal cavity. It seemed to me that by this method (and it alone) sufficient space would be obtained to get out the ovaries and tubes, as they could plainly be felt in the pelvis. I then took a pair of strong scissors, and using two fingers of my left hand to open the incision, cut open the abdomen until the wound extended some two inches above the umbilicus. The tumor was then drawn upward and forward through the incision, and the left ovary coming into view was ligated after considerable trouble, and cut off with the tube. The left ovary was found stuck on to the side of the tumor low down in the pelvis, and so incorporated with the growth that, after several ineffectual efforts to tie it, it was for the time let alone. Just at this moment Dr. Neale, who had been holding the tumor for me, informed me of the fact that it contained fluid, and upon palpation this was evidently the case. As the removal of the ovaries for a cyst could do no good, and had never been done so far as I knew by any one, I decided, before taking any further step, to consult Prof. J. Edwin Michael and Dr. B. B. Browne, who were present, and who very kindly assisted me during the operation. Both of these gentlemen agreed that the best thing to be done was to take out the tumor and the uterus. Any clamp not being large enough to embrace the pedicle, consisting of the cervix and part of the tumor, I decided to do the intra-peritoneal operation after the manner of Martin. As there was no adhesion, a common elastic drainage tube was carried around the base of the tumor two or three times, and was skilfully adjusted by

Dr. Neale, so as to cut off the circulation. To prevent any chance of hemorrhage a very stout silk ligature being passed through the pedicle as low down as possible, the stump was tied as tight as the string could be drawn, being thus divided into two parts. The cyst having been tapped, and a basin full of fluid withdrawn, I took a scalpel and amputated the tumor along with the uterus above the vaginal junction, a sound having been previously adjusted in the bladder to prevent injury to that organ. So well was the circulation controlled by the elastic ligature that not a drop of blood escaped. It now remained to trim out the tissue from the stump, so that the centre would become shaped after the manner in which the core may be cut out of an apple. This was done in such a manner as to leave the centre of the stump hollow, with the circumference projecting upward like a raised rim to a barrel. Sutures being passed through this rim from before backward, the two lips were securely drawn together, with the peritoneal surfaces in apposition, just as the two edges of a clam-shell rest one upon the other. The elastic ligature was then removed, and after passing one more suture so as to stop a slight oozing in one corner of the stump, the remaining ovary was removed, and the abdomen closed up. The woman seemed to experience no immediate shock, the pulse being nearly as full and strong after the operation as it was before. During the succeeding night she suffered slight pain, which was quieted with a fourth of a grain of morphia given hypodermically. Pulse during the night and succeeding morning beat 110 or 115 to the minute, and I felt much encouraged. During the second day, however, the pulse became too frequent, and at the same time irregular and weak, the abdomen began to be very tympanitic and sensitive to pressure, and the heart gradually becoming weaker and weaker, she finally died early on the morning of the third day.

At the post-mortem, very kindly performed for me by Dr. Abbott, it was demonstrated that peritonitis had set in, the intestines being much distended and the peritoneum red in patches. The abdominal incision was very nicely adherent throughout its whole length; the bladder was uninjured, and the only abnormality discovered was from five to six drachms of bloody serum found in Douglass's pouch. This serum came, I suppose, mostly from the stump, although it is possible a part of it may have proceeded from the peritonitis.

At no time was temperature over 101½°. It seemed to me death resulted from nervous prostration. If she had died within twelve hours after the operation, with the same symptoms, I should have attributed it to ordinary surgical shock. As to whether the few drachms of serum found in the peritoneal cavity could have caused acute septicæmia, is a question I do not feel able to decide positively. Formerly we were taught that septicæmia did not develop until as late as the sixth or seventh day after the operation, but I am informed by Professor Howard that Dr. Keith teaches it may appear in some cases as early as forty-eight hours after operation. If such be the case, it is probable that some of the patients heretofore treated for peritonitis and bound up by opium, ought to have been let loose with a pair of scissors and washed out with a pail of water. Just when is the proper time to re-open a closed up abdomen is often not easy to decide. If in the case here reported the few drachms of serum in the peritoneal cavity caused the fatal result, that result would have been obviated by drainage. The symptoms, however, did not point to what we ordinarily call septicæmia. I am inclined to think that in any case where adhesions are general, where part of the cyst's contents have escaped into the peritoneum, where the bladder or intestine have been wounded or cut open, where part of the cyst has been left behind, or where, from any cause, the result of inflammation may produce blood poisoning or septic peritonitis, that it would not only be good surgery to leave in a drainage-tube, but if necessary, reopen the abdomen and wash out the peritoneal cavity, and that, too, as early as the second, third, or fourth day after operation, according to the severity of the symptoms. It would do no harm, and might do much good. The antiseptic used in this case was the bichloride of Hg.; that is to say, the instruments were thoroughly scrubbed in a one to two thousand solution of this drug, and afterwards only clean water was used to wash, sponge, etc. In concluding this very short report, I may take time by the forelock, and answer by anticipation a question that will surely be asked, viz.: But why did you take out the uterus with the tumor? Of course one could not be taken out without the other. One step of the operation unavoidably led to another. To gain any knowledge whatever concerning the ovaries, it became absolutely necessary to turn the tumor outside of the abdomen. Then, and then only, was it discovered that the growth was cystic, and that the extirpation of the ovaries would do no

good. It would have been about as difficult to return a child to the cavity of the uterus, after having been once delivered, as it would have been to have attempted to return this tumor into its bed in the abdomen; it was accordingly extirpated. Fibro-cysts of the uterus are very rare, and the literature upon the subject is scanty. Among the colored race, I have read of no similar case, nor does any book with which I am acquainted give the history of such an operation in a colored woman.

Medical Societies.

THE PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated meeting, November 22, 1886. The Vice-President, Charles K. Mills, M. D., in the chair.

Dr. E. C. Seguin, of New York, read by invitation

Notes on Three Cases of Tropical Beri-beri, and on Some Similar, American Cases. (*See page* 65.)

Dr. H. C. Wood made some remarks on the

Diagnosis of Neuritis,

and showed two illustrative cases.

Dr. Charles K. Mills then made some remarks on

The Concurrence of Multiple Neuritis with Myelitis or Encephalitis.

As one result of the interest which has been aroused in the subject of multiple neuritis, or polyneuritis, some cures have been effected which were before not considered possible; but it seemed to the speaker that, as in the case of other advances in medicine, some have been led to go too far in their conclusions, and have overlooked facts which are worthy of close attention. That multiple neuritis frequently occurs, can no longer be doubted; but that it occurs frequently as an absolutely isolated affection is, to say the least, doubtful. His own experience was, that not infrequently either myelitis or encephalitis, or both, concur with this affection; that is, not a few cases in which the diagnosis of multiple neuritis could be made by the strict rules applicable to the study of this affection—by a certain combination of motor and sensory symptoms, by their localization in distal parts of the limbs, and by tenderness of the nerve trunks, and of the muscles—positive evidences of the existence of the central disorders were also present.

If, as is generally believed, multiple neuritis is the result of a direct toxic influence on the nerve-elements themselves, it was reasonable to suppose that this same influence would frequently be exercised upon the nerve elements of the brain and spinal cord.

Gowers, in his *Manual of Diseases of the Nervous System*, says, with reference to the cases of multiple neuritis which have been pathologically examined:

"The *spinal cord* has been found healthy in most cases. The ganglion cells, in most instances, have presented abnormal appearances, a vitreous appearance, or vacuolation, and this when the anterior nerve roots were not diseased. Now and then more considerable changes, usually those of chronic myelitis, have been found in the cord. They are probably merely coincident. Morbid appearances in other organs are common in the cases of alcoholic origin. The brain will present signs of chronic meningitis. The liver is frequently, and the kidneys are occasionally, found diseased."

Dr. Mills' conclusions were that we may have four classes of cases:

1. Cases of multiple neuritis, pure and simple; such cases, however, were rare.
2. Cases in which the multiple neuritis was associated with myelitis.
3. Cases in which multiple neuritis was associated with encephalitis.
4. Cases in which multiple neuritis was associated with both myelitis and encephalitis.

Instead of the association being just as is indicated by this classification, the combination might be of neuritis or peri-neuritis, with meningo-myelitis or meningo-encephalitis; or, finally, any modification of these combinations might be found.

Dr. Mills referred to a case which he had seen in consultation recently, in which the patient presented all the typical marks of multiple neuritis, the condition of her limbs being such as to call to mind the picture in Gower's recent book of a case of multiple alcoholic neuritis, with palsy of extensors of wrist and flexors of ankle. This patient had also very positive evidences of cerebral involvement—mental confusion, with hallucinations and delusions both of sight and hearing. She had a clear history of abuse, not only of alcohol, but also of opium, chloral, and other narcotics. He believed that in this case there was a concurrence of multiple neuritis, with a similar pathological condition in the spinal cord and brain. He also referred to other cases, seen in consultation, and more particularly in the Phila-

delphia Hospital, where the majority of patients have been the victims of alcoholic excess—cases in which a confused picture of nerve, cord, and cerebral disease, probably inflammatory, was frequently presented. Cases of poisoning by lead, mercury, and particularly arsenic, were also discussed. Particular reference was made to the series of cases of poisoning by arsenic which he reported to the College of Physicians of Philadelphia in 1883.

A most interesting case, as bearing upon the views here presented, was one which he saw with Dr. O'Hara, of Philadelphia, to whom he was indebted for notes of the past history of the case, and also for suggestions as to the condition present at different stages. This patient, a professional man of originally good physique, and of remarkable intellectual attainments, had, eight years ago, an attack of rheumatism, which left him with a crippled heart, the damage to this organ, however, not seeming to have been of its valvular, but rather of its nervous structures. The patient was in the habit of using tobacco and alcohol, but not to excess, and sometimes did not use these agents at all for long periods. Two years after the first attack of rheumatism he began to have trouble with his vision. Sight in both eyes slowly failed until he scarcely had more than perception of light in both eyes. Careful ophthalmoscopic examinations were made with negative results; the media were clear, and no signs of retinitis or neuritis were discovered. In eighteen months he entirely recovered his sight from travel, rest, and the use, in the latter months, of strychnia hypodermatically injected. About a year after recovery of his sight he had another attack, rheumatic or rheumatoïd gouty in character. In this attack he had insomnia and evidences of general nervous irritability. At this time the left upper extremity suffered from an undoubted attack of neuritis, affecting the most of the brachial nerves, but more markedly those of the median distribution.

About six months ago, he had what appeared to be an apoplectiform attack, his left side—face arm, and leg—being temporarily paralyzed, but without unconsciousness. The attack passed off in a few hours.

About two months since he was engaged in work which called for both mental and physical effort, and considerable exposure. One day, when at a height of more than one hundred feet, he was suddenly stricken with incomplete paralysis of motion and sensation in the lower extremities, accompanied by great pain, but succeeded by his own efforts in getting again to the ground. This attack he attributed, probably correctly, to a stroke of air. On examination, he was found to have almost complete paralysis of the left leg from the knee downward, with blueness and coldness of the foot, and typical anæsthesia dolorosa as high as the ankle. He complained of excruciating pains, which he described as "jamming" in the sole of the foot. The right leg showed a similar condition, but much less marked, the paralysis of motion and sensation extending only half way to the knee, and not being nearly as complete as upon the other side. In two weeks, under the use of anodynes, local and general, with massage and weak currents of electricity, he recovered completely from these symptoms in his limbs. He then began again to use both head and limbs without rhyme or reason, and was attacked with loss of power and great pain, and perverted sensation in the right leg below the knee, with swelling of the dorsum of the foot and of the ankles. He also began to have lightning pains, here and there, in both lower extremities, and radiating from the spine upward, these being sometimes accompanied by retraction of the head. Still later he developed symptoms of cerebral excitement—total insomnia, refusal to take medicine, quasi-delusions, great loquacity, etc. He was without sleep for nine days and nights. Various remedies were vainly tried, but the first genuine relief which he obtained was from hypodermic injections of morphia, repeated every twelve hours. This was followed by the administration of deodorized tincture of opium regularly every four hours, in doses of from ten to twenty minims, with twenty minims at bed-time. This treatment was continued, with digitalis, which he had been taking more or less for six or seven years, for about nine days. Mild alcoholic stimulus was also used, and nourishment was systematically administered. He was improved to such an extent that all the symptoms, neural, spinal, and cerebral, have greatly diminished, so that he is able to travel, but he cannot yet endure any great strain, either physical or mental.

Dr. James Hendrie Lloyd read

Notes on the Electro-Diagnosis of Neuritis and Anterior Polio-Myelitis.

Dr. H. C. Wood stated his belief that chronic multiple neuritis is one of the most frequent of the severe organic nerve diseases, and that in a large proportion, of cases of serious nerve disease, the whole spinal axis and its accessories are affected. In general paralysis of the insane, four-fifths of

the cases have some lateral or posterior spinal sclerosis, and a large proportion of these cases, no doubt, have multiple neuritis. He thinks that it is perfectly proven that locomotor ataxia may travel down the cord and produce peripheral neuritis, and that it is equally well proven that periperal neuritis may travel upward, producing secondary lesions in the cord. With reference to electrical studies, it may be said that a large number of cases show that in the various forms of neuritis, every possible change in the electrical reactions can be found. Post-mortem examinations are sufficiently numerous to show that peripheral neuritis is frequently not associated with other diseases, and that it frequently causes symptoms which simulate other affections. When we have peripheral neuritis, it is difficult to make out a spinal trouble back of it.

Dr. Osler thought that it was clear that we have the curious disease beri-beri in this country. It is probable that it exists in the Gulf States, as, a few months ago he received some slides, which had been sent by a physician of Texas, and were said to contain the micro-organism of beri-beri. Any one reading the descriptions of this disease must have been struck with the remarkable resemblance of some of the cases to acute ascending paralysis. His friend, Dr. Vineberg, now of New York, who formerly practiced in the Sandwich Islands, gives a very accurate account of the suddenness of onset, the rapidity of the ascension of the paralysis, which, in some cases, ultimately involves the respiratory muscles, producing death in that way. He agreed with Dr. Wood that multiple neuritis must be an exceedingly common disease. The French journals of the current year contain a surprising amount of literature on the subject. He had been particularly interested in cases of neuritis occurring in connection with certain of the fevers. After typhoid fever it has been described a number of times, and also after phthisis. During the past year, he has had one interesting case of paralysis of the extensors of the left foot in connection with phthisis, unquestionably a case of neuritis. He suggested that possibly some of these cases of paræsthesia of the hands, with feelings of numbness and tingling, which Putnam has described so accurately, may be of the nature of a peripheral neuritis. A case recently presented itself at his service at the Infirmary for Nervous Diseases, in which these symptoms were very marked, and in which there apparently were some trophic changes. The skin was glossy, and the hands were somewhat swollen, and, indeed, they presented in a slight degree the appearances seen in myxœdema.

In connection with the diagnosis between acute ascending paralysis, anterior myelitis, and multiple neuritis, he would refer to an article by Francotte in the *Revue de Médecine*, to which attention was called in the *Medical News* of July 3, 1886. He reports four cases, two of which were studied anatomically, and in which the cord was found to be absolutely normal. In these two cases the clinical picture was that of Landry's ascending paralysis.

Dr. Seguin said that he was much interested in the remarks of Dr. Mills as to the possible coëxistence of a central with a peripheral lesion. He had no doubt that this coëxistence is frequently a source of considerable difficulty in making up our minds whether a case is one of irregular poliomyelitis or of peripheral neuritis. It also seemed to him to be a matter of great practical importance as regards treatment that we should make up our minds whether we have a case of perineuritis or one of parenchymatous neuritis. The former disease, which is, he thinks, the more common, and perhaps present in some cases of so-called neuralgia, is essentially an inflammatory change in the connective tissue, perhaps penetrating into the interior of the nerve bundles, but not affecting the nutrition of the axis-cylinder or myelin, and not capable of producing any distinct paralysis or atrophy. The diagnosis may be made clear by relying on this distinctive point, that in interstitial neuritis there must be anæsthesia, even if limited in area; and a true paralysis and atrophy, even if restricted to a few muscles. In perineuritis the symptoms are more diffused, milder, more subjective, and do not present a specific appearance. He thought that Dr. Lloyd had struck the key-note in insisting on the importance of a careful study of the neural and muscular reactions. In true neuritis and interstitial neuritis, there must be degenerative reactions in some shape, distal from the point of disease, while in perineuritis and in some forms of myelitis, the reactions are either irregular or simply a quantitative or nodal reduction.

The diagnosis is of great importance with respect to treatment. Perineuritis and meningitic conditions he treats with great energy with counter-irritation, and with the actual crutery and blisters. Internally, he employs mostly tonic treatment, and does not resort to mercury or iodide of potassium unless there is a special reason for their use. Rest

is also an important element in the treatment of perineuritic conditions. In essential neuritis, therapeutic measures can have but little effect, as we know that a natural repair takes place irrespective of artificial conditions. If we favor nutrition by our general remedies, that is the most that we can do, although galvanism may serve to keep up a better nutrition in muscles pending nerve regeneration.

In regard to the relation between neuritis and beri-beri, he did not wish to be understood as stating positively that we have beriberi among us, but he thought that it would not be out of place to call attention to the analogy between the symptoms of the two affections. He thought it well to have the attention of physicians in our Gulf States called to the features of the disease. As the disease has recently appeared in northern Brazil, it may appear in our Southern States.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, November 26, 1886.

The Vice-President, Dr. Clara Marshall, in the chair.

Dr. John B. Roberts reported a case entitled

Recovery after Abdominal Section for Purulent Peritonitis.

A woman, æt. 44, came under my notice with the following history: About eight weeks ago she was seized with violent pains in the abdomen, which pain has been constant ever since, with occasional griping and colicky sensations. There has been no vomiting, but for three weeks past she has been restricted entirely to liquid food by her physician. There has been no chill.

When first seen by me she stated that some three weeks previously she had been seized with great pain in the abdomen during the night, and about that time she had noticed in the left side of the belly a mass or tumor. I could get from her no definite history of the tumor, nor of any previous abdominal disease. Her health, previous to the present illness, had been good. At the time my attention was called to her by Dr. Arthur J. Meigs, she had a temperature of over 102°, and a pulse of about 130. From the flushed face, thighs flexed upon the pelvis, the considerable pain on palpation of the abdomen and the adynamic condition, it was very evident that the woman was suffering from peritonitis, due, in some way, to this tumor. Accurate examination was not practicable on account of the pain which it caused, and the woman's condition was too weak to permit any extensive or elaborate means of diagnosis being instituted. The tumor was smooth in outline, and apparently about the size of a fœtal head. A vaginal examination showed the uterus to be not much out of the normal position, although the fundus seemed to be tilted somewhat forward. My diagnosis, made in a provisional way, was a cyst of the left ovary of, perhaps, several months' duration, which had ruptured, allowing the contents to escape into the abdominal cavity. It was possible, of course, that the peritonitis was due, not to rupture of an ovarian cyst, but to some other form of tumor, or to disease of the fallopian tubes.

Under the belief that removal of the tumor and cleansing the peritoneal cavity of the contents of the tumor which had been thrown into it, would afford the best chance of recovery, I was induced to call a consultation as to the propriety of doing an abdominal section.

Accordingly, on the following day, with the consent of the other members of the surgical staff of the Pennsylvania Hospital who were present, I made an incision through the linea alba, extending almost from the umbilicus to the pubes, and at once came upon a smooth tumor, containing fluid. Puncture of this with the trocar evacuated some five or six ounces of very offensive pus. The intestines and omentum were adherent to the surface of this sac, which was evidently the rounded mass felt through the abdominal wall. It was soon apparent that there had been a long-standing inflammation, involving the structures contained within the abdominal cavity. It was impossible to enucleate this large sac or cyst because of the matting together of all the structures, and the large amount of new tissue which had formed as the result of the inflammatory process.

Although great care was taken, and a good deal of time consumed, I was unable, either by hand or by means of a bougie introduced as an explorer, to determine the original site of the growth, or the reason for the beginning of the inflammation. There were a number of similar sacs or cysts containing pus, whose walls were made up of adventitious tissue and the neighboring viscera. In fact, all the contents of the left side of the pelvis were glued together by inflammatory adhesions and new-formed tissue. As it was found impossible to remove all the new tissue, or to tear up all the adhesions, I was

content with scraping out the most accessible portion of the sac wall, evacuating the pus from the numerous other cavities, and with washing out the abdomen very thoroughly with a solution of bichloride of mercury, containing one part of the salt to ten thousand parts of water. The abdominal wound, which was about five inches in length, was approximated by catgut sutures. Two rubber drainage-tubes were inserted at the lower angle of the wound, and a dressing of iodoform and corrosive sublimate gauze applied.

The whole operation was done under the strictest antiseptic precautions, and the patient was then put to bed. For two days she received no food, liquid or solid, being allowed simply cracked ice, and an occasional small dose of morphia and brandy. Subsequently she was given small quantities of milk and such easily digested food. On and after the second day a solution of corrosive sublimate of the same strength as that used at the time of the operation, namely, one to ten thousand, was used for washing out the abdominal cavity through the drainage-tubes, but the upper portion of the wound dressing was not removed. The temperature gradually fell to normal, which point it reached on the fourth day. At this time the upper portion of the dressing was removed for the first time, and complete union was found of the upper portion of the wound.

Three weeks after the operation she was discharged, by her own request, from the hospital, although she had not yet regained sufficient strength to be able to move about the room. In fact, we kept her in bed up to that time, fearing that the exhaustion of getting up might be deleterious to her.

During the last week of her stay in the hospital, a portion of the incision re-opened artificially. At the time of her discharge, the opening into the abdominal cavity appeared to be closed, though there was still a small superficial wound at the lower portion of the original incision.

This case of suppurative peritonitis, due to an unknown cause, cured by operation, is a good illustration of the advances in abdominal surgery. Although I did the operation under the impression that the origin of the trouble was an ovarian cyst, I should have been willing to do so had I known the exact condition of the disease, because such an encysted peritonitis as this evidently was, with the symptoms present, was almost certain to be followed by death. At least, this is the reasonable conclusion when we consider the condition of the patient's temperature and pulse, and the fact that the peritonitis was so intense that her thighs were flexed upon her pelvis. I had, in fact, every reason to believe in a speedy termination of the case.

Operations upon the abdomen have recently been performed for so many causes, with such a high percentage of success, that it seems to me probable that many cases of peritonitis, more or less resembling this one, can very successfully be treated by abdominal incision, and an evacuation of the purulent contents of the belly.

My experience in abdominal section and suture of the intestines for stab wounds, and the experience of Bull, Hamilton, and others, in a similar treatment of gunshot injury of the belly, together with my results in exploratory abdominal incisions, have convinced me that we are too ready to allow patients to die from intra-abdominal injuries. Rupture of the bladder, stab wounds of the intestines, gunshot wounds of the intestines. traumatic rupture of the intestines, peforating ulcer of the stomach, and even, perhaps, perforations due to typhoid fever, should be treated in many cases by immediate opening of the belly and local surgical measures.

This case is a contribution to the literature of the subject, to be added to the many cases similarly treated by gynecologists. General surgeons do not, I think, fully appreciate the advantages which are gained by imitating our gynecological brothers in the adoption of active surgical treatment for abdominal injuries.

Mary Willits, M. D.,
1527 *Green St.* *Reporting Secretary.*

THE CLINICAL SOCIETY OF MARYLAND.

Stated meeting held October 15, 1886.

Discussion on Supra-vaginal Hysterectomy for Fibro-cyst of the Uterus in a Negress. (*See page* 69.)

Dr. B. B. Browne was much interested in Dr. Chunn's report. He had seen the operation, and it was skillfully done. Don't think Dr. Chunn could have pursued any other course. In his opinion death resulted from septicæmia. Asked if the woman had ever taken ergot, as it had been claimed that cystic degeneration is common in fibromata after the administration of ergot. In some respects Dr. Chunn's case resembled one that he had had about two years ago. It occurred in a colored woman, and from its ap-

pearance was a prolongation upward and an enlargement of the whole fundus uteri. The tumor was probably a fibroid change in the fundus itself.

Dr. L. DeL. Gorgas asked asked why Dr. Chunn did not tap the tumor before removing it from the abdomen.

Dr. W. P. Chunn, in reply to these questions, said, that the woman had taken ergot at different times, but had never been on a systematic course of this treatment with the object of destroying the growth.

He did not tap before removing the tumor from the abdomen, because the indications of the presence of fluid were so slight that he did not detect it at that time. It is not infrequent for a small amount of fluid in a tumor to resist all efforts at detection through the abdominal walls. Don't think any of her symptoms pointed to death from septicæmia.

Dr. B. B. Browne said the question often arose as to the propriety of operating upon young women suffering from these tumors. In his opinion it is eminently proper. He thinks it gives them a longer lease of life.

Dr. R. Winslow said, he took for granted that septicæmia following abdominal operations did not materially differ from septicæmia following general surgical operations. There were cases in which septicæmia developed rapidly, and terminated fatally without any very marked rise of temperature; moreover, it is not necessary for a larger quantity of fluid to be found post-mortem or for this fluid to be ill-smelling, to prove that the patient died of septic poisoning. We must bear in mind that there are two distinct conditions grouped under the term septicæmia, one due to the absorption of a certain amount of putrefactive material, the symptoms being due to *quantity* of the morbid material which has been absorbed. The poison in this case is *chemical*, and is of the nature of a *ptomaine*, and is formed in some way through the agency of the ordinary germs of putrefaction, the bacterium termo. The other condition is a *septic infection*, and is due to the entrance of *pathogenic germs*, micrococci and bacilli, which rapidly increase after gaining entrance into the system. In this case the secretions need neither be bad smelling, nor of large amount, as the poisoning is not due to the *quantity* of the poison absorbed, but to the *quality*. He did not see any reason to disagree with Dr. Browne's opinion that the woman died of septicæmia, and that this was due not to inefficient drainage, or absorption of decomposing fluids, but to the entrance of specific germs, which the atmosphere of a general hospital is always loaded with.

Dr. O. J. Coskery said that Erichsen, in his last edition, mentions a case of septicæmia, following upon a gunshot wound, that proved fatal in three days.

Dr. J. H. Branham thinks some cause for the peritonitis should be pointed out.

Stated meeting held November 5, 1886.

Vesico-Vaginal Fistula, Vesical Calculi, Dilated Ureters and Suppurating Kidneys.

Dr. C. F. Bevan presented the above specimen. The patient first came under observation in September, 1871, suffering from stone in the bladder. She gave the following brief history of her trouble, viz:

Elizabeth A., æt. 36, married, no children, good family history. Her trouble dates back some six years, and is by her ascribed to a difficult labor which was terminated by forceps. Following the labor extensive suppuration ensued, by means of which the posterior wall of the bladder and upper and vaginal wall sloughed. Gradually symptoms of pain, bloody urine, and general vesical uneasiness had developed. She was examined by Dr. Bevan, September 17, 1871; a stone was at once recognized. The vagina at that time was found to be a mere cul-de-sac without any trace of uterus, though this organ could be felt per rectum, and could be plainly made out by bi-manual palpation. On the left upper side of vagina an opening leading into the bladder was made out, through which most of the urine leaked.

September 19, 1871, the urethra was rapidly dilated, and a phosphatic calculus weighing one and a half ounces was removed. She made a good recovery, and regained full power over the bladder in forty-eight hours.

When the finger was in the bladder, at the time of operation, search was made for the uterus. The neck could not be found, but at one side of the bladder a *puckered*, constricted opening was felt; it was believed to be the uterine stump devoid of cervix.

October 10, operation was done for the closure of the vaginal fistula. Unfortunately the operation failed, though the size of the fistula was diminished.

She reappeared December 15, 1873, and a stone weighing half an ounce, of phosphatic character, was removed; again, November 26, 1878, stone a half ounce; September 9, 1880, stone a half ounce.

The patient entered Bay View Hospital and died there October 7, 1886. From the official report of the autopsy the following account is condensed:

"E. A., age fifty-five, etc. The genitalia were removed, together with the kidneys; bladder small, cavity almost obliterated and filled by a large rough stone firmly fixed; the vagina was opened posteriorily about three inches from the anus. It ended apparently in a cul-de-sac. Into this there was an opening on the left side as large as a pea; a calculus projected into this opening. The uterus was cut open from above. Its mucous membrane was red and gangrenous, and contained some small phosphatic masses. At the lower extremity of the uterus there was a large dilatation, whether belonging to uterus or vagina could not be made out. In this dilatation were two large calculi which were worn perfectly smooth where they were in contact. One of the calculi was directly continuous with the large stone in the bladder. The kidneys were dilated, and filled with gangrenous stinking pus; their pelves were inflamed; uterus dilated and inflamed."

It is probable that at the time of her labor the cervix uteri and posterior wall of bladder sloughed. In the process of repair the uterine stump became adherent to bladder and vagina, whilst the floor of the bladder became attached to the floor of the vagina, save at one spot, that of the fistula. Hence, the vagina became shortened to a mere cul-de-sac, the uterus emptied into a pouch behind the bladder, and thus two cavities were formed communicating with each other, viz., a part of the bladder in front and a portion of the vagina behind. The posterior pouch could not empty itself, and urine decomposed the constantly forming calculi.

DISCUSSION.

Dr. A. F. Erich said he had seen the patient during her lifetime. He did not make any examination at the time, as the woman refused to enter the hospital. Regarding the method of removing the stone in such cases, he would always dilate the fistula in preference to dilating the urethra. Several recorded cases demonstrated the serious damage that has resulted from removal of calculi through the dilated female urethra. Rather than resort to this method, he would cut through the vesico-vaginal septum.

Dr. W. E. Moseley remarked that in cases of vesico-vaginal fistula, whether created accidentally or purposely, there was a marked tendency for the accumulation of phosphates in the bladder and vagina and external genitals. This condition could, in a great measure, be prevented by keeping the urine markedly acid by the use of tinct. muriate of iron, with perhaps the addition of an extra amount of hydrochloric acid, or by the use of a solution of benzoic acid. By thus keeping the parts clean, and at the same time improving the patient's general condition, the chances following operative procedure for the closure of the fistula were greatly improved, and the danger from reformation of a phosphatic stone reduced to a minimum.

Dr. W. P. Chunn thought it a very interesting case. He was of the opinion that a stone very rarely reformed after removal through the vesico-vaginal septum, but thought that in this case the blood entering the bladder might serve as a nucleus about which the phosphates could collect; that the cases of reformation are generally those in which there is present a chronic cystitis and the phosphatic deposit is not thoroughly removed.

Dr. J. E. Michæl said he had had experience with this same patient. On one occasion he had removed a calculus partly through the urethra and partly through the fistula. After the operation the bladder was kept washed out with nitric acid as strong as practicable, but the woman being an opium eater and in every way a thoroughly unsatisfactory patient, left the hospital before any permanently good results could be achieved.

Dr. J. H. Branham thought that in the case presented it would be impossible to keep the pouch at the mouth of the uterus drained, and that the formation of calculi could not be prevented. He did not believe that the patient could be cured by any operative procedure.

Dr. A. F. Erich considered that the patient was too unmanageable to be cured by any treatment. Six years ago he operated on a case of complete loss of vesico-vaginal septum by drawing the posterior lip of the cervix down and attaching it to the anterior edge of the fistula, and by so doing the uterine excretions and menstrual blood were all emptied into the bladder. The patient has done perfectly well, and there was no sign of any stone in the bladder.

Dr. C. F. Bevan in closing the debate said that the general treatment spoken of by Dr. Moseley had been carried out as fully as was possible under the circumstances. He had found it impossible to keep the pouch at the os uteri drained, and every attempt to close the fistula had failed.

(To be continued.)

—Prof. Sappey says that the ovaries of one woman contain enough ova, if they were all fertilized, to populate a city as large as Paris.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Mental Alienation of Blue-Beard.

Under this heading the *St. Louis Medical and Surgical Journal* for August, contains the following:

Antiquarians have settled among themselves with singular unanimity that the original of Blue-Beard, the terrible and bloodthirsty old bogy that shared the honors in our nursery days with Jack-the-Giant-killer, was a certain Chevalier de Retz or Rays, who lived in the early part of the fifteenth century. A singular bit of history in relation to this monster, recently published in France, is of interest to physicians, inasmuch as it furnishes a veritable clinical observation in the study of a peculiar form of mental alienation—*folie impulsive.* It is a letter written by de Retz, after his condemnation, to King Charles VII., of France, and now published for the first time that we are aware of, in English. De Retz, or to give his full name, Gilles de Laval, Chevalier de Retz, was a most noble and powerful knight, a companion and fellow-soldier of Joan of Arc. After the tragic death of La Pucelle, he retired to his castle of Machecoul, in Brittany, and there gave himself up to the excesses and cruelties that have made his name infamous for all time. He did not, however, as told in the story, marry inquisitive maidens and murder them for gratifying their curiosity, but he did far worse, as will be seen by a letter produced below. We find the original text in a work by Julian Chevalier, on the *Inversion of Sexual Instinct, medico-legally considered*—a work already noticed in the *Journal* (February, '86, p. 87). After having murdered over eight hundred children in the gratification of his horrible passion, De Rays was finally brought before the Court of Brittany, tried, found guilty, and condemned to be burned at the stake. He appealed to the king for a commutation of sentence, in a letter of which the following is a partial translation. After the usual formalities, he says:

"I do not know how, but of my own self, without counsel of any one, I concluded to act thus (as detailed in the *acte d'acusation* and trial), solely for the pleasure and luxury it afforded me. In fact I found incomparable delight in murder, doubtless by the instigation of the devil. It is eight years now since this diabolical idea came to me. One day being by chance in the library of the castle, I found a Latin book describing the lives and customs of the Cæsars of Rome. It was written by a learned historian by the name of Suetonius. The said book was adorned with pictures very well painted, which showed how these Pagan emperors lived; and I read in this beautiful history how Tiberius, Caracalla, and other Cæsars, slaughtered children, and took pleasure in torturing them (*et prenaient plaisir a les martyrizer*). Upon this I determined to imitate the dead Cæsars, and on that very evening I commenced to follow up in earnest and carry out the text and the pictures of the book."

He goes on and recites how two of his retainers, Henriet and Pontou by name, were instructed as to his desires, and became the purveyors of victims for his horrid orgies. He continues: "I abused these children for the ardor and delectation of luxury which their sufferings caused me. Afterwards I caused them to be slain by these fellows. Sometimes I made them cut the throats of the children, severing the heads from the bodies. Sometimes I crushed their skulls by blows of a heavy stick. Sometimes I removed their limbs; removed their entrails, hung them on iron hooks to cause them to languish, and while they were languishing to death, I had connection with them. Sometimes I did the same after they were dead. Oh, I had great pleasure in seeing the most beautiful heads of these children after they were bloodied."

Further on he says: "As to those slain, their bodies were burned in my chamber, except some very beautiful heads which I kept for relics. I do not know how many were thus killed, except that the number was more than one hundred and twenty each year." Finally he appeals to the king thus: "I have often lamented that I left your service, most venerated Sire, when I did so, some six years ago; because if I had not done so, I would not have come to this; but I must confess that I was led to retire to my estate by a certain furious passion and desire which I felt toward your son, the Dauphin of France, such that I would not have failed to have slain him some day, as I have since slain so many innocent children, by the secret temptation of the devil. I conjure you, Sire, not to abandon me, your humble

servant, your chamberlain, your marshal of France. Spare me, and let me expiate my crimes by retiring to a monastery, after the manner of the Carmelites."

The prayer was not granted. Condemned to death by the court, he was burned at the stake, along with his accomplices and tools, in the town of Nantes, in 1440. The ruins of his castle at Machecoul are still to be seen. As remarked by Chevalier, we have here an example of homicidal mania accompanied by perversion of sexual instinct exactly the counterpart of cases frequently seen nowadays. Fortunately, however, they do not have the opportunity of gratifying their mania to the same extent as did the horrible monster whose story is thus related. Those were days of demonomania, of sorcery, of beliefs in incubi and succubi, and an almost universal priapism. Crimes against nature could not fail to be the most common events, and the result was the monstrous phenomenon "Blue-Beard."

An Experimental Study of Mycotic or Malignant Ulcerative Endocarditis.

Malignant ulcerative endocarditis is a form of lesion always associated with some kind of bacteria. The causative relation of these bacteria to the lesions are points upon which Dr. T. Mitchell Prudden seeks to throw some light in a paper in the January number of the *American Journal of the Medical Sciences.*

Dr. Prudden shows that bacteria are frequent in a certain proportion of cases of acute ulcerative endocarditis in the cardiac, and, when these exist, in the peripheral lesions. These bacteria are small and of spheroidal form in almost all of the cases thus far described; but in a few cases the presence of bacilli has been noted. There are cases of ulcerative endocarditis with extensive destruction of tissue and large formation of thrombi, in which the lesions are entirely free from bacteria. In these cases, as a rule, the endocardium is the seat of an old inflammatory process, and the peripheral embolisms, infarctions, etc., do not contain bacteria. In many cases of acute ulcerative endocarditis associated with bacteria, the valves and endocardium are also the seat of old inflammation.

The destructive process and formation of thrombi in the heart-valve and endocardium may be as marked and extensive in the cases in which the bacteria are absent as in those in which they are present; but in the latter class of cases the embolic lesions which are apt to be developed are of an infectious nature, and the general course of the disease is apt to bear the stamp of an acute infectious disorder.

The gross appearance of the valvular lesion does not always or usually enable us to distinguish between these two forms of disease. Bacteria are sometimes present in cases of acute vegetative endocarditis, but in the lesions of chronic proliferative endocarditis they do not appear to occur at all. The bacteria which are present in the cardiac and peripheral lesions in cases of malignant ulcerative endocarditis are the causative factors in the disease. The bacteria apparently produce the cardiac lesions by lodgment on the surface of the valves and endocardium, when the latter are rendered vulnerable to their action either by mechanical or chemical injury; or by the presence of old inflammatory alterations; or by conditions unknown to us. Bacterial embolism of blood vessels of the heart-valves is apparently not of frequent occurrence, as was formerly believed.

The only bacteria which have been thus far absolutely identified as occurring in the lesions of malignant ulcerative endocarditis in man are streptococcus pyogenes and staphylococcus pyogenes aureus. This identification has been made in six cases. Dr. Prudden has demonstrated that other species of bacteria than those mentioned are capable of causing similar lesions in rabbits under similar experimental conditions.

Finally, Dr. Prudden points out that, in view of the significant relationship of the bacteria of pyæmia and suppuration to malignant ulcerative endocarditis in the cases thus far fully examined, it is evident that a demonstrably diseased condition of the heart-valves, or a previous history which would suggest the possibility of such a condition, should be an additional incentive to the practice of a vigilant antisepsis in operations, however simple, upon this class of cases.

Loose Cartilages in the Knee-joint.

Dr. William J. Shaw thus writes in the *Brit. Med. Jour.:*

W. W., aged 27, was admitted into Glasgow Royal Infirmary, September 6, 1886, suffering from loose bodies in the knee-joint. His occupation was that of a moulder, which he had followed for eleven years, during which time he has had to work almost continually on his knees. Twelve months ago his attention was drawn to his knee-joint, in which he felt a very severe pain, or, as he described it, "a kind of grip." The pain increasing in severity, he requested admission to the hospital for the purpose of getting

something done, as neither by night nor day had he relief from the excessive agony he was suffering. Examination in hospital showed that the right knee-joint was very much swollen as compared with that of the left side; this swelling being due to the presence of a number of loose bodies of considerable size, one of them being nearly as large as the patella itself, and all being freely movable from one part of the joint to another. The feeling conveyed to the hand on grasping the joint and moving it, was the sensation produced by feeling a number of marbles in a bag. The affected joint was rather hotter to the feel than the healthy one. There was no signs of inflammation; and there was no history of rheumatism.

On September 12th, the joint was opened under strict antiseptic precautions, and twenty-two loose cartilages were removed. The total weight of these bodies amounted to 1,681 grains; they varied in weight from 230 grains to 20 grains. The largest body measured fully an inch and three quarters in length, by an inch in breadth, and an inch in thickness. The bodies were white in color, and were of different sizes, one or two being as small as a boy's marble, the majority of them being of considerable size, up to an inch and three-quarters in length, fully an inch broad, and an inch thick. All were formed alike of smaller rounded masses stuck together like the lobes of a conglomerated gland, each body being distinctly rounded on its outer surface, but flattened on its lateral, or inner adherent surface. A large part of the outer surface of one of the largest masses had undergone calcareous degeneration. On cross section, the surface presented a distinctly laminated character, the outer laminæ being firm, bluish white in color, and about a quarter of an inch in thickness. This disclosed a slightly darker and softer part, which occupied the centre; and the two parts might be distinguished as the cortical and medullary portions. Opaque spots were formed in both the cortical and medullary parts, which were obviously due to calcareous degeneration.

The microscope showed that the structure of the bodies was that of fibro-cartilage, in which the fibrous element was comparatively scanty and the hyaline was predominant. The cells of the latter were arranged in large irregular masses embedded in a granular matrix, which were surrounded and only slightly traversed by fibrous tissue. Numerous patches of calcareous degeneration were found which seemed to affect chiefly the granular matrix of the cartilage.

The individual bodies were carefully weighed by Dr. Du Moulin and myself, and subjoined I give the weight of each cartilage: 230, 200, 170, 90, 90, 90, 80, 75, 70, 60, 60, 57, 56, 51, 49, 50, 44, 40, 40, 37, 22, 20 grains—1,681 grains.

The patient made very satisfactory progress after the operation, his temperature remaining normal all through; the dressing was not changed till October 9th, twenty-two days after operation, when the wound was found to be healed, the drainage-tube (which was a decalcified chicken-bone) having become absorbed. Dry dressings were applied.

October 11th. The patient left the hospital able to walk perfectly well, but was advised to wear an elastic bandage for some time to support the joint.

Common Sense.

Before an English medical society (*Brit. Med. Jour.*, Nov. 6,) Mr. Lawson Tait gave an address on this subject. Commencing, he said that he regretted, during his struggles in early life, that there had been no teacher at Edinburgh in his time who had taught them the application of common sense in the practice of medicine. This was regarded as the most uncommon of all the senses, and that perhaps was as easy a definition and as accurate a one as any that could be formulated. A man possessed of sterling common sense seemed to him to be one who was best able to take in any matter, and particularly free from personal bias and prejudice; and as personal bias and prejudice can only be lessened by subjugation of self, it came to be really that the man who had most common sense was to the largest extent capable of subjugating his own interests to those of others. As with a man, so with a body of men; and very largely on this point humanity seemed to judge those who were banded in various subdivisions of the lines of life, as professions, corporations, or other methods by which were accomplished the multitudinous objects with which we are concerned. These bodies were frequently the subject of jests, and such jests! Whilst they were not by any possibility true of the bulk of men, constituting the particular walks of life in question, yet, even when deserved, they formed beacons and guides for action, pointing out the direction which correctness of conduct should avoid. Against our own profession, such criticisms were frequent enough, and, in some individual cases, they were unfortunately found to be deserved. As, for instance, when a member of our pro-

fession took advantage of his position of trust to destroy some fellow-being in whose removal he was interested. Then his professional brethren pursued him as relentlessly, and detected the poison with as much care, as if he were one for whom they were far less concerned. In fact, as bodies in such cases, we subjected all consideration of self to the establishment of the higher interests of others in the whole community. The result of this was that no set of men had such a complete hold on the public confidence as the medical profession. Passing from our corporative life to our individual existence, it was probably less true of us that we were able to subject our individual interests to the interests of others than it ought to be. The want of our capacity to do so involved us in the individual disputes with which nearly every individual life was chequered. In our youth, this fault was much more prominent than in our middle life or old age, for we were inclined to fall into two cardinal blunders in starting the race of life. The first of these was a tendency to look upon every patient who consults us as something in which we had a proprietary right; the second was a tendency to resent every kind of infringement of this right, especially in the matter of the patient being inclined to see some one else without our knowledge. The conclusions to be drawn from these errors are—first, that no one had any proprietary right to any patient. Every patient had a right to consult one man or twenty if he might be so disposed, without letting the other nineteen know that he had consulted any particular one. Secondly, that no one had a right to refuse to meet in consultation any practitioner of decent life and character to see whom it might be the wish of the patient. If these two errors were well taught, we should have less squabbles between consultants and general practitioners, such as had recently been evident in the medical journals to a very large extent.

A New Method of Excision of the Knee.

Before the Medical Society of London, December 6, 1886, Mr. Herbert Allingham read a paper and showed cases of a new method of excision of the knee. The operation consists in making a vertical incision over the joint in front, beginning two or three inches above the patella, and prolonged over the patella down to the tubercle of the tibia. The knife splits right through the quadriceps tendon above the patella into the synovial pouch there. The soft tissues over the patella are divided to the bone, the knee-cap sawn through, dividing it into two lateral halves, then the ligamentum patellæ is also split down to the tubercle of the tibia. By this means the joint may be thoroughly exposed by drawing outwards each half of the patella and associated structures to its corresponding side of the joint. The two halves of the patella are wired when the operation is finished. He claimed the following advantages for the operation:

1. The attachments of the fascia lata, the lateral ligaments, and the prolongation of the vasti to the tibia and fibula, are not divided, and consequently there is much more support to the joint during the healing process, and when the leg is well.

2. Above the patella the synovial pouches are well opened, and all the synovial membrane can be thoroughly removed.

3. Dislocation of the tibia backwards and tilting of the femur forwards, which commonly occur after the operation, are thus prevented.

4. The joint and the end of the bones can be thoroughly examined, which was not possible by the method of lateral incisions.

5. The undivided quadriceps is a strong antagonist to the ham-string muscles, and should the splint be left off the leg is much less likely to become bent.

6. Progression is greatly improved, the attachment of the quadriceps being neither divided nor the muscles shortened, as must necessarily take place when either the transverse **H** or **U**-shaped operation is performed.

7. And, above all, as we hope after excision to obtain movement in the knee-joint, the chances, Mr. Allingham thought, of such a result being brought about will be greatly facilitated by the operation described.

In future operations Mr. Allingham said he would remove thoroughly the whole synovial membrane, and only dig out with a gouge the diseased spots on the cartilage, and should not in any way interfere with any of the cartilage that looks healthy. If the crucial ligaments are not extremely diseased, they should be left undivided. The joint should be kept at absolute rest until the wound has healed, when passive motion may be commenced.

Mr. William Adams thought nothing could be better than the result in the case shown.

Mr. Edmund Owen considered that the hemorrhage would be less from the joint in Mr. Allingham's method, which he should certainly practice, but rather as erasion than excision of the joint.

Mr. J. H. Morgan always avoided excision as far as possible, and this would certainly be obtained by Mr. Allingham's method, which he hoped in future to try.

Mr. Allingham, in reply, said that a good view of the whole of the interior of the joint could be obtained.

On the Advantages of Gymnastic Exercises in the Horizontal Position, in the Treatment of Lateral Curvature of the Spine.

Mr. William Adams read a paper on this subject before the Medical Society of London, in which he recommended a combination of the various systems of treatment, such as recumbency, muscular exercises or gymnastics and mechanical support, in place of relying upon any one system exclusively. The degree in which they were combined must vary according to the case, age, and other circumstances. For gymnastic exercises in the horizontal position, he had recently employed an improved exercising plane, made by Mr. Ernst, at his suggestion; this apparatus he exhibited to the society. The plane was six feet in length, and made on an incline, having a sliding board, half the length, fitted with pulleys, and movable up and down the inclined plane in grooves at the side. The exercise consisted essentially in the patient drawing himself up the inclined plane, while the body was resting on the sliding board or movable stage. This movement might be repeated several times, say from five to ten times a day at the commencement, with intervals of rest, and gradually increased, but always avoiding fatigue. Dr. John Shaw was the earliest advocate of horizontal exercise, and gave an illustration of an exercising plane, in his work on the subject dated 1823. This was modified by Amesbury, but the plane exhibited comprised Mr. Shaw's plane, with several useful appliances for special exercises. By a combination of recumbency and gymnastic exercises, and the addition of mechanical support in some form best adapted to the requirements of each case, deformity might be remedied in the earlier stages, and its progress arrested.

Mr. Edmund Owen expressed some disappointment with the paper. He thought the use of mechanical supports tended to prevent the growth of muscles, and preferred rest and proper exercise carried on under surgical supervision.

Mr. Bernard Roth said that the methods advocated by Mr. Adams were neither new nor useful.

Mr. James Black mentioned two cases which had been markedly benefited by postural treatment and rest.

Mr. Walter Pye said that it could not be doubted that cases did exist which could be treated only by mechanical support, and therefore that it would not be justifiable to discard the treatment entirely.

Mr. Baker and Mr. Benham took part in the discussion, and, in reply, Mr. Adams maintained that in many cases where structural changes had taken place in the vertebræ, the treatment by muscular exercise was altogether inadmissible.

Goitre in the Himalayas.

Dr. Giles, of the Indian Medical Service, who is the medical officer to Colonel Lockhart's expedition, has contributed a short paper to the *Indian Med. Journal* on goitre in the Himalayan regions. He states that the disease is endemic throughout a large portion of the northwest Himalayas and the Hindu-Kush ranges, and that in the endemic areas about five per cent. of the population are affected. As a general rule the disease first showed itself about puberty, but cases beginning in childhood, in early adult life, or even in middle age, were not uncommon. The most interesting point in the paper is an investigation of the question how short a residence in a goitrous district might be followed by goitre. The garrison of Gilghit afforded an opportunity of obtaining data, for the men were partly recruited from districts where goitre is endemic and partly from districts where it is not. Ganesha Singh, the medical officer of the Maharajah of Kashmir's "Ruddur" regiment, furnished Dr. Giles with statistics, which showed that sixty-one men out of a total of 800 were affected with goitre. This is equivalent to a little over 7.5 per cent. Twenty of these men came from districts where goitre was not endemic, and the condition had developed subsequently to their arrival in the Gilghit-Astor command. The average period of residence previous to the appearance of the goitre was 12.7 months, the shortest period being 5, and the longest about 19. Comparing these figures with those for recruits from goitrous districts, Dr. Giles comes to the conclusion that previous residence in such districts had no predisposing influence, for the average duration of residence in thirty-seven men in whom the disease had appeared after their arrival in Gilghit was 12.32 months. In discussing the etiology of the disease, Dr. Giles states that the most char-

acteristic geological features of the district are ranges of granite and gneiss. The disease is most prevalent where timber is most scarce, and where the natives live in dark unventilated mud huts. Two apparent exceptions are explained by the fact that the houses are large, with good chimneys, and built of stone. No cases occurred among the members of Colonel Lockhart's expedition, who were well lodged, and lived under good sanitary conditions. Want of ventilation and, in general, unsanitary conditions are necessary antecedents, without which, Dr. Giles concluded, the specific cause of the disease is inoperative, and by attention to the former, the latter may be defied.

Cocaine for Morphiomania.

Two cases have recently been observed in Cairo of temporary hallucinations after prolonged subcutaneous use of cocaine, as recommended for abuse for abuse of morphia injections. The second case occurred in the person of a European doctor, and only lasted two days, during which it was believed that some harmless servants were persecuting him. It now appears that he was accustomed to take morphia injections himself, and was invited to take charge of the first case during his temporary restraint. This first case has been reported by a Greek, Dr. Comanos, in the *Berliner Klin. Wochenschrift* (No. 38), who watched the patient throughout. After being addicted to the morphia habit for several years, he recommended his patient, a middle-aged European of excitable temperament, to take as a substitute three-quarters of a grain of cocaine, hypodermically, three times a day. The pain and distress occasioned by the lack of morphia was relieved by this, but the patient gradually and privately increased the dose until he took every day eight and even twelve grains. This induced great mental irritability, singing in the ears, dyspnœa, and hallucinations, which all disappeared upon returning to injections of morphia. But, unfortunately, a painful attack of herpes zoster ensued, and the patient doubled his former cocaine injections to sixteen and afterwards twenty-three grains a day. The symptoms produced by these large doses were trembling of the limbs, lassitude, incontinence of urine, loss of sleep and appetite, excitement, hallucinations, injected conjunctivæ, and a very fixed expression. He believed that burglars lurked in his garden, and he fired revolver shots at imaginary figures by night, eventually nearly strangling one of his servants because he believed he had swallowed a lantern. He was then removed to a hospital, and, on being searched, cocaine, morphia, and many hypodermic syringes were found on him. His drug treatment consisted of three-quarters of a grain of morphia subcutaneously injected three times a day, and in forty-eight hours he was perfectly sane again, and prepared to explain away his hallucinations, especially those of sight and smell.

The Density of the Teeth as Influenced by the Food, etc.

Dr. W. D. Miller of Berlin, has recently communicated to the American Dental Soety of Europe the results of his experiments upon dogs, to show the effect upon the teeth produced by the absence or presence of lime salts in their food. Every dental surgeon knows that the hardness of the teeth may vary greatly in the same individuals at different periods; the most marked, although by no means the only cases, are those of pregnant women; and this cannot be explained solely on the ground that the secretions of the mouth are vitiated by reduced acid from gastric disturbance. There is undoubtedly an absolute softening of the whole tooth substance, due, probably, to the robbing of the teeth of the mother of their lime salts in order to build up the osseous system of the fœtus. Dr. Miller is endeavoring to show experimentally how far changes can be produced in teeth. His *modus operandi* is to extract a tooth from a healthy dog, and then to feed the animal upon food containing but little lime salts for three months; a second tooth being now removed, the food is changed to one containing an excess of salts. This is continued for four months, when a third tooth is extracted. From the results of chemical analysis, he finds that there is an appreciable loss of lime salts in the first stage, amounting in one case to more than 1 per cent., and during the second stages that the proportion of lime salts rises to normal. The number of experiments has not been sufficient to give absolutely conclusive results, and no microscopic examinations have been made. Dr. Miller himself points out that Zalesky and Hoppe-Seyler, in their similar researches, maintain that the bones are not only deficient in lime salts, but that there is an absolute rarefaction, so we should expect some similar change in the teeth. We should also like to hear of some experiments on pregnant animals.

Manaca in Muscular Rheumatism.

Dr. Thomas P. Gary thus writes in the *Med. Age:* I have treated quite a number of cases of muscular rheumatism, which is getting to be very common in this country, and in no instance have I had any reason to complain of the results obtained from the use of manaca.

It will only be necessary to give a history of one case, for its effects have been uniform throughout. The patient had been a sufferer for quite a number of years, and had tested the talents of distinguished physicians without receiving any material benefit. He had suffered much from malaria for four years, and physicians differed as to whether he had any syphilitic complication. If there was, it most probably was the result of vaccination during the war, as he presented no evidence of having contracted it in the usual way.

He was out shooting one day, during a small rainfall, and although he did not get very wet, a pain of a neuralgic character began in the region of his right nipple, and he became feverish and quite nervous. Subsequently he was under treatment by physicians, but was often annoyed by neuralgic pains in various portions of the body, but more particularly in the muscles of the chest and back, occasionally in legs and arms. Any extra exertion produced them, though subacute. He was subjected to constitutional treatment of iodide of potassium and mercury, without any material benefit, for several years, and finally came under my observation. I prescribed fluid extract of manaca in 35 and 40-drop doses three times a day. This he continued for two months, and the improvement was gradual and permanent, and to-day he expresses great confidence in being entirely cured. The duration of this "disease," the failure on the part of other physicians to relieve with standard medicines, his condition, and the great improvement under the use of manaca, certainly should encourage us to give this remedy further trial in these cases.

Spermatorrhœa.

In the *Boston M. and S. Jour.* (Dec. 2), Dr. M. A. Richardson reports a case: The patient has ejaculations on the slightest provocation, the touch of a razor to the face being enough to cause one. He also complains of ejaculation during defecation. A specimen of the fluid lost during this act had been secured and was shown to the meeting. It proved to contain spermatozoa. Before seeing Dr. Richardson, cold sounds had been used for three years, and deep injections, both without effect. The patient asks to have the prostatic urethra cauterized, and Dr. Richardson is inclined to make use of this treatment.

Dr. Watson said that he thought that physicians underrated the frequency and importance of true spermatorrhœa, which was generally treated as existing chiefly in the imagination of the patient, the thick, gummy discharge, of which they complained as occurring at the end of urination or during defecation, not being examined microscopically. If this be done, a certain number of specimens will be found to contain spermatozoa, generally dead, owing to having been passed back into the bladder and lain for some time in the urine. The mental depression and hypochondriasis associated with this condition, as well as a train of symptoms too long to enumerate here, that are generally observed in this malady, are very marked, and constitute its most difficult feature in treatment. The actual local condition, which consists in hyperæmia and disturbed innervation, is generally greatly improved by large cold steel sounds, or the hollow sound rendered cold by a current of water, and deep injections of nitrate of silver —never stronger than five grains to the ounce, and preferably one or two grains to the ounce. Dr. Watson did not believe in cauterizing the prostatic urethra in these cases, a practice originating with Lallemand, and thought that it might eventuate in stricture.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Several lectures by Dr. Thomas G. Morton, of Philadelphia, on the Antiseptic Treatment of Wounds have been reprinted, and will be found of unusual interest.

——The *Pittsburgh Medical Review* began its career in December, 1886. It is a monthly, with twenty-eight reading pages; price, $1.00 a year.

——The "History of Medicine and Medical Men in Camden County, N. J," by Dr. J. R. Stevenson, of Camden, makes a large 8vo. of 39 pp. It is a careful summary.

——The *American Journal of Biology*, edited by Dr. H. D. Valin, is a quarterly which begins with a promising number. Price, $1.00 a year. The editor's address is 802 South Halsted street, Chicago.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

RUBELLA.

While the broad lines separating measles and scarlatina are universally recognized, there has been anything but harmony among writers concerning certain anomalous forms of eruptive fever prevailing from time to time which present mingled characters of the two affections, or which appear to present the features of an independent affection. Ever since the middle of the last century, they have attracted much attention, and while, for the most part, they have been considered as aberrant forms of measles or scarlatina, there can be noticed a constantly recurring disposition to gather together, under a special designation, certain cases occurring sporadically or epidemically, which seemed to offer peculiarities distinguishing them from these two diseases. Gradually all affections having a red macular eruption, and not recognizable as measles or scarlatina, came to be described as rötheln, and great confusion resulted, but within the last twenty years the question has assumed a phase that gives hopes of its satisfactory solution.

The last writer on the subject is Dr. I. E. Atkinson, who, in the January number of the *American Journal of the Medical Sciences,* studies the disease in a systematic manner, both historically and clinically. His conclusions are that

1. Rötheln is a specific, contagious, eruptive disorder.

2. While it possesses characteristics which, taken together, justify a reasonable degree of certainty in its diagnosis, it has no symptom that may not be and is not often assumed by measles.

3. A sporadic case, occurring in one who has never had measles and who affords no history of exposure to rötheln, may be diagnosticated with a fair degree of confidence, but not with absolute certainty.

4. The unqualified diagnosis of rötheln should only be made during an epidemic in which all persons exposed, irrespective of former attacks of measles, are liable to be affected, and in whom the symptoms follow a pretty uniform type. In the absence of a pronounced epidemic influence, a series of cases occurring in a household, a school, or an asylum, showing typical symptoms, may be diagnosticated as rötheln with a fair degree of confidence.

5. In sporadic cases, where neither measles nor rötheln has been experienced, a diagnosis of probable measles or rötheln must be made, as conditioned by the resemblance of the symptoms and course to the type of one or the other affection.

WHY BOVINE VIRUS SOMETIMES DISAPPOINTS.

We have recently become cognizant of a fact in connection with the traffic in bovine virus that tends to explain why it not infrequently happens that points procured from a reliable vaccine farm fail to give the satisfaction that is expected of them. It often happens that a druggist will buy a case of points, out of which he sells a few and then the demand temporarily ceases. He has been instructed that the virus will become inert after a certain time (two weeks, we believe), and he is told to return all points not used within that time, for which fresh ones will be forwarded. He thinks that he will not bother the parties from whom he has bought them, so he puts them away in his cellar, thinking that because it is cold there, they will retain their efficacy. After a while a doctor comes along who wants to vaccinate some one; he is furnished with one of these inert points, and, of course, the vaccination fails "to take." He tries again, with the same result; his patient blames him, he blames the druggist, and the latter determines to buy no more points from this particular farm; while in the minds of all who are cognizant of the transaction, a doubt is thrown upon the efficacy of bovine virus. See how much trouble and undeserved censure results from the druggist's failure to do that which he has been plainly directed to do. It is not right that good bovine virus should be thus unjustly brought into disrepute.

To prevent such mistakes in future, we would suggesst that wherever practicable the physician should order direct from the farm, or he should at least be sure that he uses only *fresh* points. There is no reason for the druggist to sell stale virus, because, as we have said, the reliable farms are not only willing, but anxious to supply fresh points for those that have become inert, for they know that only thus can their reputation be maintained. This is a very serious matter to all concerned—to the producer, the druggist, the doctor, the patient, and the whole community—and we wish to most earnestly impress it upon our readers.

A LESSON OF GENERAL LOGAN'S DEATH.

Of all statistics, certainly *vital* statistics are obviously the most valuable, since from them are to be gathered deductions of *vital* interest and value to humanity. *Reliable* vital statistics, we would say, are inestimably valuable, while those which are unreliable are worse than worthless—they are damaging, because they are misleading. Now then let us ask, have we any reliable vital statistics in this country? No, we certainly have not, and they are unreliable because in recording deaths physicians frequently fail to accurately state the cause of death. Thus in the case of the late General Logan, his death is attributed to "rheumatic fever." Now, it must be evident to any one who stops to reflect, that he did not *die directly* of "*rheumatic fever.*" He, no doubt, had rheumatism, and we take it for granted he had fever, as it is an accompaniment of acute rheumatism; therefore it is correct enough to say that he had "rheumatic fever," if you like the term, but it seems to us much more likely that his death was due to endo- or pericarditis; or, since he has been subject to rheumatism for some time, and, from rumor, has not been well for months, his death may have been due to cirrhotic kidneys, a frequent termination of the gouty diathesis, especially in those who have reached General Logan's age. How frequently do we see, in mortality reports, death attributed to *convulsions*, yet we all know that a convulsion is but a symptom of some cause. Occasionally we see *paralysis*, as a cause of death; is it not absurd to make such a statement? Uræmia is frequently given as a *cause*, when it is but an *effect* of the kidney disease that has caused the fatal issue. So we might go on, but we have said enough to illustrate the point, that when a physician assigns a *symptom* as the *cause* of death, he may satisfy the relatives of the deceased, but he is committing a sin against the community, by giving them false premises from which to draw their vital deductions.

A LESSON FOR MEDICAL MEN FROM THE MESSAROS CASE.

An exceedingly nasty scandal that was recently tried in this city contains a lesson of interest to physicians. The Rev. Waldo Messaros was the pastor of a church to which a certain woman belonged. There are many collateral circumstances in the case, but the one fact with which we have to deal is that this woman invited the clergyman to her house, and he went, unaccompanied by any one, and while the two were alone in the parlor she made an outcry, and declared that the man had assaulted her. The case was tried in court, and the minister was acquitted. His defence was that this was a conspiracy to have him removed from his charge. He claimed that he had suspicions of the woman's designs, yet he had the temerity to visit the woman alone. The lesson we wish to draw is the same we have

pointed before. The physician who conducts his treatment of women privately is always liable to a similar difficulty. Of course, such a charge is very rarely made, when we consider the very large number of persons so treated; but the danger is ever-present, and no one knows at what moment it may become a reality, or who may be the victim. The lesson is that when a physician is obliged to treat a woman confidentially, he ought (if we may be pardoned the Hibernianism) to have a third party present.

Notes and Comments.

Scald of the Larynx in a Child; Tracheotomy; Recovery.

For the following account we are indebted to Mr. Edward Harrison, house-surgeon, who reports it in *The Lancet:*

Charles C——, aged two years and four months, was admttted on Jan. 2d, 1886, at 6:30 p. m. At 2:30 p. m. on the day of admission he attempted to drink from the spout of a kettle containing boiling water.

On admission there was some cyanosis and sucking in of the lower ribs during inspiration. He was at once put into a tracheotomy cot, with a steam kettle, in a warm room. At 8 p. m. the symptoms were much relieved. At 9 p. m. he became much worse; there was much cyanosis and sucking in of the chest walls during inspiration, and the breathing was stridulous. Tracheotomy was performed, and at once relieved him.

On the following morning the temperature was 103.4° F. This came down gradually day by day. For the first few days there was much bronchial discharge, so that the tube had to be cleared with a feather about every five minutes. His pulse was 150, and respiration 60 to 80. He was treated with brandy, ipecacuanha wine, and aromatic spirits of ammonia, and had poultices applied to the chest. On the 19th the silver Bryant's tube was changed for an india rubber one, in which a hole was cut to allow of respiration through the larynx. On the 22d he wore a cork in the tube all day, and on the 23d the tube was removed and the wound allowed to heal. The after-progress was uninterruptedly good. He was discharged on Feb. 5th, well.

Purple Suffusion of the Extremities Alternating with Attacks of Hæmatinuria.

Dr. Tannahill thus writes in the *Brit. Med. Jour.*, December 18:

M. N., aged five, female, has been subject to attacks of hæmatinuria for three years. The attacks occur after a chill, and are more frequent in cold weather. Between the attacks the arms and legs become, as the parents say, black and cold, pain is complained of, and apparently some loss of power in the legs and feet. These interim attacks are also associated with chill. The hands and feet, as far as the ankles, become of a deep purple tint, equally diffused and not disappearing on pressure. There are pain and tenderness in the parts affected. No sweating or swelling. The skin assumes a healthy appearance, and the pain subsides in less than thirty minutes. The urine looks normal, and is free from albumen. There is no real loss of power in the legs, but movement is restricted to avoid pain. Ross describes a somewhat similar condition under plantar neuralgia (*Diseases of the Nervous System*, first edition, vol. 1, pp. 517–18), and he cites a case of Weir Mitchell's, in which the upper and lower extremities were affected. The alternation of hæmatinuria with vaso-motor disturbance of the extremities in this case suggests a common origin of both.

Bearing in mind the reciprocity of skin and kidneys, a vaso-motor paralysis, similar to that observed in the extremities, may occur in the kidney, great congestion would ensue, and the coloring matter might escape. The short duration of the attack, in each affection, is reconcilable with temporary vaso-motor disturbances.

A New Local Anæsthetic.

Drumine is the title of a new Australian local anæsthetic discovered and described by Dr. John Reid, of Port Germein, South Australia (*Lancet*, December 18, 1886). Euphorbia drummondii is the species from the milky juice of which the alkaloid drumine was prepared. Cocaine is known to have a mixed action on sensory and motor nerves, and causes preliminary excitement; whilst drumine is said to have an almost purely sensory paralyzing effect, and does not cause excitement. Experiments were made on cats and on the observer's tongue. It was injected into the legs of the former animals and caused general dullness, with marked impairment apparently of all forms of sensibility. Placed on the tongue, nostrils, and hand of the observer, the resulting anæsthesia was most marked. The alkaloid has no action on the pupil, and small doses given internally produce no constitutional effect. It has been employed successfully in subcutaneous injections for sciatica and sprains.

The experimentation has so far been imperfect and incomplete. We hope soon to have a fuller account of this new alkaloid, and to be able to give further information thereon. The amount injected subcutaneously was four minims of a four per cent. solution. Dr. Reid anticipates a brilliant future for the drug in the domain of nervous and cerebral diseases.

Contagion of Tetanus?

At the Société de Chirurgie an interesting paper, followed by discussion, was read by M. Larger, which seemed to show clearly that there were good grounds for believing in the contagiousness of tetanus. Four patients who had been treated in the Colmar Hospital were seized with tetanus at different intervals, and all died. The nature and severity of the wounds varied in each case from an amputation to a simple incised wound. The only thing common to them all was that the cases had all occupied contiguous beds. Tetanus is rare at Colmar. None of the patients had had anything to do with horses. A veterinary surgeon, M. Cagnat, had practiced castration on horses for twenty-five years without a single case of tetanus. At the end of 1884 he removed with an écraseur a tumor of the testicle in a horse; the animal died of tetanus. Operations for castration practiced with the same écraseur on five horses afterwards were followed by tetanus and death in all the animals. The écraseur was then submitted to disinfection by being heated to a high temperature. The instrument was afterwards used for fresh castrations, and without tetanus resulting in any of the animals operated on.

Chloride of Methyl in Neuralgic Affections.

Dr. Dudley Tait thus concludes an article in the *Kansas City Medical Index:*

1. Chloride of methyl spray may be used with great advantage in all neuralgic affections; its sole indication is *pain.*

2. It can be successfully resorted to in view of eradicating *pain* in the course of various pulmonary affections, in acute and chronic rheumatism, and also in affections similar to the writer's cramp, etc.

3. In trifacial neuralgia, precaution is of absolute necessity, but does not constitute a counter indication.

4. One application often suffices; however, two and exceptionally several applications are necessary.

5. The majority of neuralgic affections are definitely cured by this treatment: success has sometimes been obtained in neuralgias symptomatic of Pott's disease, pelvic tumors, etc.

6. The slight and *transient* pigmentation that sometimes follows this treatment is of no importance; it disappears in the space of two weeks.

7. Experiments seem to indicate that the analgesic properties of chloride of methyl are due to its action on the superficial terminal expansions of the nerves of the skin.

Bone Grafting.

At the French Congress of Surgery, M. Poncet expressed the belief that it would be possible to reconstruct a destroyed bone by means of osseous grafts. It is not after cicatrization that the grafting can be expected to succeed; it is at an anterior period, when active healing of the wound is taking place, that the grafting can be made under the most favorable conditions. M. Poncet then cited the case of a child of eleven, from whom a long sequestrum of the tibia had been removed after osteo-myelitis. This sequestrum measured twenty-five centimetres in length. One month after the operation the first attempt at grafting was made. The fragments were taken from a newly-born infant which had just died. Antiseptic dressing was used, and the limb was kept at rest with plaster splints. Twelve days later the dressing was changed; there was slight suppuration. New grafts, composed of four bony fragments, were then procured from a young kid. These were implanted in fleshy granulations and only one was eliminated. Six months after the operation there was a solid bony mass, thirty centimetres in length; the child became strong and able to walk.

Hydrocarbons in Hypodermic Injection.

Dr. Albin Meunier has made a communication to the Société des Sciences Médicales of Lyons, to which the *Semaine Médicale* calls attention, on the use of vaseline as a vehicle for the hypodermic injection of different essences. Eucalyptol, menthol, essence of cubebs, of sandal, of copaiba, and other substances, may be so administered, witnout untoward symptoms. It is said that these injections give rise to no local troubles and very little pain. For the drugs mentioned one part in five of vaseline is used after filtration repeated three times. For thymol the proportion is one in ten. It has also been found that vaseline dissolves creasote, iodine, camphor, sulphide of carbon, carbolic

acid, iodoform (when in previous solution with the essences), and even the alkaloids. For some of these the quantities given are as follows: iodoform, one to eighty; sulphide of carbon, one to fifteen; creasote, one to twenty; iodine, one to twenty; cocaine, one to fifty; digitaline, one to a thousand.

Effects of Petroleum on Health.

Dr. Bielczyk publishes in a Polish medical journal the result of his experiences among the workers in petroleum wells. Very violent mental symptoms are produced by acute poisoning by the gaseous exhalations existing in the shafts of the wells, amounting to delirium of a maniacal character. These, however, always quickly cease when the patient is brought up to the earth's surface. Speaking generally, the mortality amongst the workmen is not particularly high; they seem to be remarkably free from diseases of the respiratory organs, both of an inflammatory and tubercular character, and also from infectious diseases. They are, however, subject to an eruption like acne, affecting the extremities. Dr. Bielczyk mentions that he has found raw petroleum an excellent application for fresh as well as for old and foul or torpid wounds.

Treatment of Whooping-Cough.

The following method of disinfection of sleeping and dwelling apartments and clothes is recommended by M. Mohn in the treatment of whooping-cough. It is said to cure the cases immediately. The children are washed and clothed in clean articles of dress and removed to another part of the town. The bed-room and sitting-room or nursery are then hermetically sealed; all the bedding, playthings, and other articles that cannot be washed are exposed freely in the room, in which sulphur is burnt in the proportion of twenty-five grammes to the cubic metre of space. The room remains thus charged with sulphurous acid for five hours, and is then freely ventilated. The children return the same day, and may sleep and play in the disinfected rooms.

Case of Menstruation after Removal of Pregnant Uterus and Appendages.

Lawson Tait thus writes in the *Lancet*, December 18:

E. P., aged thirty-three, menstruates somewhat profusely at irregular times, and has done so twice in the last three weeks. This has continued since I removed the uterus (at the fourth month of pregnancy) in August, 1884. A large soft sarcoma grew from the fundus, and the whole uterus was infiltrated with nodules of the same growth; therefore the clamp was made to include as much of the organ as could be pulled up, and I believe the whole of the organ was removed. Previous to the operation, she tells me that she never had any sexual enjoyment, but that now she has it occasionally. The vagina is now (Nov. 22, 1886,) greatly elongated, and a small pimple can be felt at the upper end of it, in the cicatrix.

Saccharine.

Saccharine, which has recently been introduced into therapeutics as an excessively sweet material, three hundred times sweeter than glucose, is likely to prove of considerable service. According to Aducco and Mosso it has very high antifermentative and antiseptic properties. It is recommended for internal administration to diabetics, with a view to rendering their food more palatable. It passes unchanged through the organism, and may be detected in the urine in its original condition. In cases of indigestion or where the intestines are the seat of abnormal fermentations and acidity, it is extolled as an antiseptic.

Antipyrin as a Hæmostatic.

At a meeting of the Geneva Medical Society, Dr. Goetz stated that, following the recommendation of Dr. Huchard, he used antipyrin as a hæmostatic in three cases of bleeding. One was a case of severe and prolonged epistaxis in a young man suffering from hæmorrhagic purpura; the second was a case of bleeding from the gums after the extraction of a tooth; and the third was a case of metrorrhagia from uterine fibroid. In the two former cases the drug was employed locally in solution; in the third, one gramme of antipyrin was incorporated in a gelatine pessary.

Vaccination Scars.

A writer in the *Correspondenz-Blatt für Schweizer Aertze*, No. 18, 1886, who had a good opportunity of studying vaccination scars at the Basle Federal Athletic *Fête* (*Turnfest*), draws attention to the æsthetic aspect of the "art of vaccination." Very many of the men had ugly, thick, and broad scars, reaching sometimes down to the elbow. When spoken to about the matter, they expressed indignation at the disfigurement inflicted upon them by the vaccinator. The writer recommends that more attention should

in future be paid to this matter, which, though trifling in itself, may sometimes strengthen the hands of anti-vaccinationists.

New Method of Employing Electricity in Neuralgia.

Dr. Adamkiewicz describes in the Polish journal *Przelad lekarski* an exceedingly effective way of applying electricity for the relief of neuralgia of various kinds. The apparatus he uses is a constant current battery, the cathode being a concave metal plate lined with electrical carbon, which is saturated with chloroform. This is then applied over the painful spot, and a current, weak at first but gradually increasing in strength, passed. One or two applications of this kind were found, says the author, sufficient entirely to relieve the severest cases.

Faradization in Jaundice.

Dr. Henri Secretan, of Geneva, Switzerland, recently treated a case of catarrhal jaundice in a child, aged 11, by faradization of the gall-bladder. The disease had not yielded to three weeks' treatment with ordinary cholagogues. The flow of bile was reestablished after three daily sittings, each of ten minutes' duration. A small cylindrical electrode was introduced into the rectum for the length of 8 centimetres, while another was applied in the region of the gall-bladder. In the intervals between the faradic sittings, large enemata, consisting of one litre of cold water, were administered.

Analysis of Urine in Abdominal Tumors.

At the French Congress of Surgery, M. Thiriar, of Brussels, speaking of the analysis of urine in cases of abdominal surgery, stated that in benign tumors the proportion of urea in urine is always more than twelve grammes, whilst in malignant tumors there is always hypo-azoturia. In support of this opinion he mentioned several cases in which he was able, by this indication alone, to diagnose a tumor as benign or malignant, which was afterwards confirmed by the operation, the necropsy, or the subsequent course of the tumor.

Transplantation.

M. Dubousquet recently related a case at the Biologlcal Society in which he had used grafts from the epidermis of a frog to heal the ulcers resulting from severe burns on the foot, caused by molten metal. For the sake of comparison one ulcer was treated with grafts taken from the patient's own skin, the other from that of the frog. In both cases four cuttings were applied, about the size of a half-franc piece each. Cicatrization took place more rapidly in the ulcer treated with the skin of the frog, and the scar is more supple than the other.

Tin Oleate for the Nails.

Thomas H. Irquhart writes to the *Therapeutic Gazette:* "I used the tin oleate some months ago on my finger-nails, which commenced to split and break soon after I left the army, the result of scurvy contracted in the military service. I anointed the nails every day with the oleate, and at night applied it on a narrow flannel bandage. In about two months all the nails were sound and tough. I applied the oleate to the nails of a young lady friend with like success. It is also a beautiful polish for the nails."

Ecchinocœa for Typhoid.

Dr. H. C. F. Myer writes to the *Kansas City Medical Index* that no quinine, whisky, or opium would be required in the treatment of typhoid if the medical profession would give tincture of ecchinocœa angustifolia, or as it is commonly called, black samson root, a trial. The fever will be reduced by it, and it is antiseptic. By its external and internal use it will lower the temperature, will shorten the course of the disease, and will save the life of the patient.

Correspondence.

Expulsion of Tape-worm.

Eds. Med. and Surg. Reporter:

In your issue of December 18 I notice an inquiry by "S. R. O., M. D.," as to the method employed by quacks to expel tape-worms. I do not know what charlatans use, but I have on my desk as I write a tænia solium, which was expelled recently after one dose of oil of pine needles, without any preliminary treatment or fasting. I believe the customary seventy-two hours' fast does more harm than good, and that the longer the fast is continued the more firmly the tænia attaches itself to the tissues, and that the patient will starve to death sooner than the worm will. I believe that to the prolonged fasting is due the irritable stomach, which sometimes seriously complicates the case and renders tæniacides inoperative and sometimes dangerous.

The case just alluded to was that of a

girl six years of age. She had been nearly starved to death, and fed on male fern and kamala nearly a year before without benefit. When I was consulted, I prescribed ʒss. of oil of pine needles and ʒss. of syrup of acacia at bedtime, eating nothing for supper except salt meat, and ordered the dose repeated the next morning before eating, the child to take a cathartic at 11 a. m., if its bowels did not move before that time. The next morning the father brought the worm to me in a bottle, and said it was passed the first thing in the morning, before the second dose was taken.

If "S. R. O." should try the oil, which can be obtained of any wholesale druggist, I should be pleased to hear whether he is successful with it or not. I used it one year ago on a woman thirty years of age, also successfully. E. O. Bardwell, M. D.

Emporium, Pa.

Chloroform in Parturition.

Eds. Med. and Surg. Reporter:

In an interesting article in a late number of this journal, December 18, 1886, on "Chloroform in Parturition," by Dr. P. I. Farnsworth, this inquiry is made: "Who would do turning or *introduce* instruments without the aid of an anæsthetic?" I am as warm an advocate of the use of anæsthetics and instruments in labor, and employ them with as little trepidation, as most practitioners; but, if it is the doctrine and practice of the profession to anæsthetize patients to *introduce* instruments, I am not in harmony with them. I have always believed, and acted upon the idea, that it was desirable to have the liveliest sensitivity of patients to aid in guiding the direction of the blades of forceps, whilst *introducing* them.

From considerable experience during a somewhat extensive practice running through nearly forty years, I am impressed that the *introduction* of forceps is a delicate operation, which requires care, involving as it does the safety of both mother and child. Once forceps are safely introduced and securely locked, there is no danger except to the perineum. *Then* anæsthetics ought to be used to a degree to prevent consciousness of pain; and intermittent traction may be made with boldness.

There is involved in this discussion a principle of great practical importance, and I would be pleased to get the views of my friend, Dr. Goodell, and other recognized leaders of the profession, upon it.

Geo. Troup Maxwell, M. D.

Ocola, Florida, Dec. 30, 1886.

A Deficiency of the Lumbar Vertebræ.

Eds. Med. and Surg. Reporter:

Was called November 29, p. m., to see Mrs. K., who was then in labor; third child. Labor progressed favorably. She was soon delivered of a female child. The other two children being of the female persuasion, she was anxious that this one should be a son. Upon examining the child I found it a nice, hearty, well-featured and well-developed child, excepting a deficiency of three lumbar vertebræ, there being no connection with the lumbar vertebra and the sacrum. The space was occupied by a very thin and transparent membrane. A portion of either kidney was discernible through this membrane. It did not appear to be painful. The afternoon of the second day there was a collection of semi-transparent fluid under this thin membrane. The third day it was more of a muco-purulent character, with indications that pus might soon form. Matters thus progressed to the tenth day, when death came to its relief. Unfortunately, no post-mortem was obtained.

From the first the child had no use of its lower limbs. The bowels and kidneys were normal in action. It nursed well, and slept most of the time. It could not lie on its back without distressing it.

I report this because of the rare occurrence of such cases, at least in my practice.

J. A. Inglis, M. D.

Morea, Ills., December 27, 1886.

Tape-worm Expelled by the Use of Turpentine and Pumpkin Seeds.

Eds. Med. and Surg. Reporter:

Samuel M., a robust lad, nine years of age, son of a farmer, commenced to pass segments of tape-worm in the spring of 1866. Late in February he came under my care. He was directed to fast twenty-four hours, and to take the following day oil of turpentine in mixture of pumpkin seeds. The patient, who varied his fast by filling his stomach with dried apples, vomited the medicine, and it failed for the time. On April 3, he fasted rigidly, and, on the morning of the day following, commenced taking the prescription given below, in divided doses—probably one or two ounces an hour. The worm, over ten feet long, was expelled in the afternoon of the same day. The prescription is as follows, except the direction for taking, which has not been preserved:

R.	Olei terebinthinæ,	fʒj.
	Ol. cinnamomi,	fʒj.
	Mist. cucurb. peponis,	ʒxj.
M.	Sig.—To be given as directed.	

The last ingredient was prepared by bruising the pumpkin-seeds in a mortar and adding water to form a mixture as thick as could be conveniently swallowed. It was strained through a coarse cloth, and the other materials were incorporated with it by trituration. The father reported the length of the worm at ten or twelve feet. He evidently overlooked the head and the filamentous neck. He presented it to me some time after, preserved in alcohol. After twenty years' immersion in this fluid it measures about five feet. The patient was henceforth free of the parasite.

E. T. Blackwell, M. D.
Cedarville, N. J.

News and Miscellany.

Inter-State Agricultural Convention, at Lake Charles.

Governor McEnery, of Louisiana, has issued a call for an inter-State convention in the interest of stock-raising, dairying, fruit-growing, and general agriculture, to be held at Lake Charles, La., on the 22d, 23d, and 24th of February, 1887.

The convention will be formally opened on Wednesday morning, after the close of Mardi Gras.

One of the most noteworthy indications of the great industrial progress of the Gulf States is the marked attention of their public men to agriculture and the efforts they are making to bring the theory and the methods of agriculture in those States into harmony with the teachings of science and the highest demands of a progressive civilization. Nature has been prodigal of her gifts to the State of Louisiana. For fertility of soil, salubrious climate, and for great variety of products, Louisiana ranks among the most favored countries of the globe.

Governor McEnery has shown commendable wisdom in thus giving the weight of his official influence to call a convention which cannot fail to be of inestimable value to the farm interest of that State and the country generally. We trust it may be widely noticed by the press, and that the results may be all the people anticipate.

This convention is so called that excursionists can remain in New Orleans till the close of Mardi Gras, and take the train for Lake Charles on Tuesday evening.

Full information in regard to the convention and the low rates of transportation, can be obtained by addressing the Secretary, S. A. Knapp, Lake Charles, La.

The Elimination of Virus from the Animal Organism.

The following is the result of observations made by Signor Trambusti on the elimination of virus from the animal organism, at the Institute of Pathological Anatomy at Pisa. The object was to clear up the still obscure point as to the elimination of the virus, and to make a special examination—(1) as to whether the elimination of a particular microbe is effected through all the secretory organs, or whether any particular organ has a predilection for a particular microbe; (2) as to whether the elimination takes place at any period of the infection; (3) as to whether the eliminated microbes still retain their pathogenic power, like those found in the blood, or whether they are expelled as dead bodies, or only modified in their pathogenic power. It being impossible to extend these complicated researches to all the diseases generated by microbes, the author confined himself to typhoid fever and malignant pustule. From numerous experiments, it appeared to result that the bacillary elements of malignant pustule and typhus are eliminated from the animal organism while retaining thetr full pathogenic power, and not as dead bodies. The author concludes—(1) that the pathogenic micro-organisms may be eliminated by the secretory glands of our organisms, through the epithelium and through the capillary vessels intact, and that some of these micro-organisms are eliminated by preference rather through one organ than through another; (2) that the elimination takes place whenever these organisms are found in the circulation, whatever may be the period of infection; (3) that the pathogenic micro-organisms which are eliminated by healthy organs always retain their infecting power.

Logan on His Own Disease.

By a peculiar coincidence, after we had written the editorial on General Logan's death, found elsewhere in this issue, we encountered the following in the *Baltimore Sun:*

"In certain quarters there seems to be some doubt as to the real cause of General Logan's death. A prominent Senator, who attended the funeral of the late President Arthur in company with General Logan, and who also occupied the same seat with the latter between Washington and New York, says that en route to New York General Logan referred to the incorrect diagnosis the eminent surgeons made in the Garfield case, and added that he believed the most

skillful surgeons often found themselves baffled in treating what they originally supposed to be cases of no serious moment. Continuing, General Logan alluded to an illness which he had about two years ago, and which his family physician said was a severe attack of rheumatism, when, in fact, the general said, he was troubled with a disease of the kidneys. It now turns out that he was frequently troubled with this complaint, and the Senator says, with all deference to the skillful surgeons who attended the general during his fatal illness, it was more likely disease of the kidneys which caused the general's death than rheumatism."

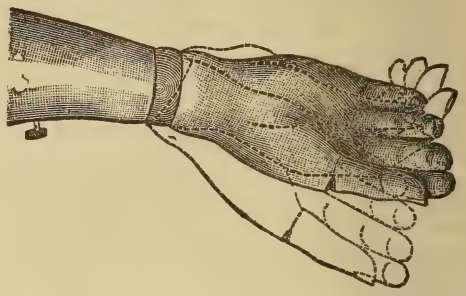
Medicinal Products of Afghanistan.

A paper was read recently before the Pharmaceutical Society of Great Britain by Dr. Aitchison, C. I. E., F. R. S., late naturalist with the Afghan Delimitation Commission, upon "Some Plants of Afghanistan, and their Medicinal Products." It appears that in Afghanistan umbelliferous plants form the characteristic type of the vegetation, the country in which they flourish consisting of great shingle and conglomerate plains lying between hills and river beds. Only about 1 out of 100 plants bear a flowering stem, and a native will assert that such a flower-bearing plant has nothing to do with the plants that yield asafœtida. The Dorema ammoniacum grows along with the asafœtida plant, and is equally abundant. Dr. Aitchison also describes as a new species (Ferula suaveolens, Aitch. and Helmsley) a plant the scented root of which, under the name of "sandal," is exported through Persia to the coast. Several kinds of manna are also produced, which are largely eaten by the people as a sweetmeat, and exported in quantity to Persia and India. Among other plants and plant products met with by Dr. Aitchison was a very handsome species of Rheum, the ripe fruit of which is used by the natives as a purgative, and Orchis latifolia (Linn.), the dried tubes of which are known as "salep."

The Transmission of Anthrax from the Mother to the Fœtus.

The *Brit. Med. Jour.* tells us that the question whether anthrax can be communicated by the mother to her offspring before birth is still undecided. Branell and others believe that the bacilli cannot pass by way of the placenta to the fœtus—the placenta, so to speak, acting as a filter, and preventing the passage of these organisms into the blood of the fœtus. He inoculated an animal during gestation with the virus of anthrax, and death ensued in two days. He then infected four healthy animals; one with blood from the dead mother, three with blood taken from the organs of a fœtus; the animal infected by the blood of the mother died next day, whilst those infected by the blood of the fœtus evinced no sign of the disorder. Strauss, on the other hand, states that he has found the bacilli in the fœtal blood, but admits that the number of bacilli found in the body of the fœtus is very small.

Artificial Arm.



The above cut represents an artificial arm with ball and socket wrist-joint, recently invented and manufactured by George R. Fuller, successor to the late Dr. Bly, of Rochester, N. Y.

The improvement admits of placing the artificial hand in any position that can be attained with the natural hand, and is an important advance in the progress of prosthesis.

An Idaho Journalist and a Burglar.

"We wish to return our sincere thanks," says the editor of an Idaho paper, "to the enterprising but misguided burglar who broke into our residence night before last, under the impression that he was cracking the crib of the druggist who lives next door. He entered at the window and carefully removed his boots, setting them down on the floor. To this circumstance, and to the fact that we saw him come in, we are indebted for the first good pair of boots we have had in ten years. While he was ransacking the house we quietly slipped out of bed, and exchanged our old boots for his, and then went back to bed and fell asleep. How long he was in the house we do not know, but the presumption is that when he went away he took the old boots. They have been missing ever since, and there was nothing else to take."

A Child's Faith in the Supernatural.

A lady living in this State is the mother of twins, little girls, about five years of age, rollicking, jolly little creatures, whom she has impressed with a degree of piety, which they carry with them in their play. Recently one of the sunny little creatures was strutting around the back yard with a rake over her shoulder, exclaiming in great glee:

"God come and take the rake! God come and take the rake!"

When her enthusiasm was at its height the teeth of the rake caught on a clothes-line, and it was switched up ont of her hand. She turned pale, but without examining the circumstances, started on a run for the house, shouting at the top of her voice: "God's got it! He's got it! He's got it!"

Precautions against Cholera.

Surgeon-General Hamilton, of the Marine Hospital Service, returned to Washington last week, from a tour of inspection along the Atlantic and Gulf coast, with a view of ascertaining what safeguards are needed to prevent the introduction of cholera or yellow fever from the south. Dr. Hamilton was accompanied on the tour by the health officers of Charleston, Savannah, Tampa, Sanford, and Jacksonville. The Atlantic coast ports were found to be well protected, but the committee decided that a quarantine hospital is needed near Key West, Fla., and Dr. Hamilton will make a recommendation to that effect. Cuba was also visited, and its entire coast line was inspected.

Whisky by the Pailful.

A wedding celebration near Lancaster (this State), rceently came to a tragic end in the death of one of the participants. After the wedding a party of young men serenaded the newly-married couple. The groom showed his generous disposition by giving them whisky by the pailful. A tin-cup was furnished from which to drink.

The deceased is said to have drunk two pints of the beverage. He soon became unconscious from its effects, and remained so until he died. He was a native of Harrisburg, and a pensioner of the late war. He leaves a wife and daughter. The coroner's jury found that he died from an overdose of alcoholic stimulants.

The Champion Eater of Iowa.

Camden, Preble county, Iowa (says the *Davenport Democrat*), has a young man who would be a terror to a boarding-house. He is a farmer lad, 16 years of age, and can do a man's work at the table. On Christmas Day he was weighed before taking dinner, then after eating and walking two miles was again weighed, and had increased his weight within a fraction of 11 pounds. He drinks a gallon and a half of milk with his meal. His friends will wager that he can do this any day, and it has been tested more than once. It is said that he is not particular what food is placed before him, so that there is enough of it. When he "falls to," everything within reach disappears as if by magic.

Rabies from the Bite of a Cat.

The death from hydrophobia of a man who was bitten by a cat in the month of August last, was the subject of an inquest at Manchester (England) recently. The man, since the bite, had complained of pains in his right arm. A medical man was sent for, and at once pronounced him to be suffering from hydrophobia. Upon this advice, the deceased was taken to an infirmary. When admitted, he was in a dying condition, and, after lingering for a short time in great agony, he expired. The verdict of the jury was in accordance with the medical evidence, namely, that the deceased died from hydrophobia caused by the bite of a cat.

An Irish Health Resort.

Surgeon-General Gordon thus writes in the *Medical Press* calling attention to Lisdoonvarna, in County Clare, Ireland, as a health resort. He says it is delightfully situated on a high land exposed directly to the winds from the Atlantic Ocean. The wells are sulphurous and chalybeate, and the waters enjoy a high reputation in the neighborhood in the treatment of eczema and psoriasis, chronic rheumatism and gout, scrofula, chlorosis, and certain forms of dyspepsia.

Preventive Inoculation Against Phthisis.

M. Vittorio Cavagius has reported to the Académie des Sciences, November 29, that a two per cent. solution of carbolic acid destroys the infective power of tuberculous virus, that a weaker solution (1.25 per cent.) enfeebles or attenuates it. By inoculation of rabbits and guinea-pigs first with inert tuberculous matter, then with attenuated, he found that they were not made tuberculous, even when pure tuberculous matter was injected.

A Cruel and Fatal Joke.

A man in Reading recently met a friend on the street who had a bottle, which he jokingly said contained old rye, and offered him a drink. He placed the bottle to his mouth, and before he could be stopped, drank some of its contents, which proved to be ammonia. His stomach and intestines were so badly burned that he became unconscious at once. His injuries proved fatal.

An Easy Labor.

Dr. S. C. Bridgewater, of Dixon Springs, Tenn., writes to the *Med. Record* that not long ago a negro woman was walking along one of the streets of that town, when suddenly labor pains began, and before she could get out of town she gave birth to a large healthy child. She picked up the baby, and carried it in her apron about half a mile to her home. She had no medical attendance during or after the labor, and both mother and child did well.

Bottle Throwing.

The dangerous practice of hurling empty bottles from the compartments of railway carriages in England, to the imminent danger of workmen employed on the line, is so largely on the increase, that the General Manager of the Midland Railway Company has again found it necessary to warn the traveling community against this stupid practice, which has often been attended with serious consequences.

Suicide and Plumbing.

A citizen in St. Louis committed suicide because compelled by the city health department to make proper connections from his house with the sewer.

Personal.

—Dr. S. R. Knight, of the Episcopal Hospital, this city, entered the twenty-ninth year of his connection with that institution last Saturday. He received many congratulations, and a host of flowers, from his friends and subordinates. His career in hospital practice is the longest of any physician in the country.

Items.

—The disagreeable odor of benzine can be removed by shaking repeatedly with plumbate of soda, made by dissolving oxide of lead in caustic soda, and rectifying. Simply shaking with charcoal and filtering will partially remove the odor.

—Dip the fingers into a strong solution of cupric chloride. In about a minute the silver will be converted into chloride, and may then be washed off with hyposulphite of soda solution.

—"My pa," said one small boy, "is a preacher, and is sure to go to heaven." "Huh!" said the other small boy, "that ain't nothin'. My pa is a doctor, and can kill your old pa."

—A man who had not the best reputation for strict veracity died the other day, and the family were greatly incensed because some well-meaning friends sent in a broken lyre as a floral tribute.

—A customer called at a pharmacy in the Rue Grenelle, says a French paper. "Give me something to get rid of worms." "Yes; what kind of worms?" "They are in my wooden leg, and are eating it away."

—Pompous physician (to patient's wife)—"Why did you delay sending for me until he was out of his mind?"

Wife—"O, doctor, while he was in his right mind he wouldn't let me send for you."

—The Vienna professorial body, having been asked by the Minister of Education whether it would not be well to place a limit on the number of students of medicine received, has unanimously pronounced against the adoption of any rule of this kind.

—The cause of death of the late Professor Panum, the distinguished Danish physiologist, is said to have been thrombosis of the coronary artery, with consequent fatty degeneration, softening, and, finally, rupture of the ventricular wall. He died at the age of sixty-three.

—The scene is a young ladies' seminary: "Ah," said one young pupil to another in triumph, "my mamma gives me a penny every morning for taking a spoonful of cod-liver oil!" "And what do you buy with the penny?" eagerly returned the second girl, in a tone not devoid of envy. "Oh," returned the former speaker, "I do not spend it at all; mamma puts it away for me every day to buy more cod-liver oil with."

—A cement for bottles containing very volatile liquids, which is easily prepared and applied, and which is said to prevent the escape of the most volatile liquids, is composed simply of very finely-ground litharge and glycerine; and it is merely painted around the joint between the bottle and the cork or stopper. It quickly dries, and becomes extremely hard, but can be easily scraped off with a knife when it is necessary to open the bottle.

Pallas Syringe."

[From the *London Medical Record.*]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche,"

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by
ROBERT SHOEMAKER & CO.

W. H. WALMSLEY & CO.,
SUCCESSORS TO R. & J. BECK,
Manufacturing Opticians,
No. 1016 Chestnut St., Philadelphia, Pa.

Microscopes,
Microscope Accessories,
Mounting Materials,
Dissecting Instruments,
Prepared Objects,

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten acres. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,
CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of recitations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

—LANDRETH'S SEEDS ARE THE BEST— NORTH, SOUTH, EAST, OR WEST!

Everything of the best. SEEDS and IMPLEMENTS for Farm, Garden, or Country-Seat. Illustrated and Descriptive Catalogues Free upon application. Over 1500 acres under cultivation growing LANDRETH'S Garden Seeds. Founded 1784.

D. LANDRETH & SONS,
Philadelphia.

VIRUS.

VERY FINE HUMAN CRUSTS OF VACCINE VIRUS can be furnished from this office at

$1 and $2 per Crust.

Address
D. G. BRINTON,

REST FOR PAINFUL EYES—IS THIS ADVICE ALWAYS GOOD?*

BY JULIAN J. CHISOLM, M. D.,

Professor of Eye and Ear Diseases in the University of Maryland; Surgeon in charge of the Presbyterian Eye and Ear Charity Hospital of Baltimore City, etc., etc.

When the eyes tire under much and long-continued use, relief naturally comes with rest, and we voluntarily desist from work so that the eyes may regain their normal condition of comfort; and this they rapidly do. This eye weariness, which comes on simultaneously with a tired feeling in the whole body, is not a painful condition. That it is a general discomfort which rest relieves, is familiar to us all as individuals, and hence we are ever ready to acquiesce in the proposal to rest our painful eyes, when such advice comes from the physician to whom we have appealed for treatment. *But is this advice always good?*

To answer correctly this very important question, eye troubles must be classified into two great divisions.

1. We have diseased states of the eyes, inflammatory in their nature, accompanied by pain with other evidences of congestion, and often associated with blurred vision.

2. This great division comprises faults in eye construction, defects in the focusing power, errors in refraction, unaccompanied by visible congestions, except on abusive use of the organ.

In one or the other of these two great classes most eye troubles can be placed.

When we see an eye that is red, watering, painful, and in many instances accompanied with blurred vision, whether this trouble be in one or in both eyes, we naturally and properly advise rest from eye work, while the inflammatory symptoms are being relieved by judicious medication. We even shut out the normal retinal stimulus, light, by smoked glasses or darkened rooms, and thereby add to the comfort of the patient.

All eyes, painful under use, are not necessarily inflamed ones. On the contrary, a very large number of the most annoying eye troubles are not dependent upon diseased conditions. The discomfort induced by the use of such eyes is occasioned by faults in the focusing power, necessitating over-use of the eye muscles, and subsequent pain in the eyes and head. Any disturbance of the system which causes temporarily general muscular debility, will diminish the force of the eye muscles and increase the tendency to head and eye pains. As these eye faults are most frequently congenital, starting with our very being, they often commence to show their injurious effects when young. Growing, and not necessarily over-strong eyes, are taxed in the acquisition of knowledge, and when the advice to rest these painful eyes for months at a time is a serious interference with school life and with education. Into this classification is brought a very large number of young persons, whose eyes are badly shaped, and hence pain in them on use.

A well-shaped eye should be nearly a sphere. In such a round eye the inner or retinal coat will receive the focused image, sharply defined, of distant objects, without

*Read before the Baltimore Academy of Medicine, December 21, 1886.

aid from the muscles of accommodation. These important muscles, within such an eye-ball, are called into use when the eye is viewing near objects. Writing, reading, and sewing are properly called eye-work, because they require the need of the accommodating eye muscles. All other uses to which the eyes are put, except the viewing of near objects, mean rest. This, of course, is not rest from retinal work, which is going on actively as long as our eyes are opened, for as a rule the retina does not seem to tire. It means rest from intra-ocular muscular work. Such a round eye is called *emmetropic*, and is the type of a good one. This is the kind of eye that nature should always supply to the human race.

Unfortunately from this standard deviations, detrimental to the comfortable uses of the organ, are found in numbers. Many children are born with eyes flattened from before backwards, so that the retina is brought too near the lens and therefore in front of its normal focus plane. This flat eye is called over-sighted or *hyperopic*. Such a flat eye, when at rest, does not see even a distant object sharply. It needs muscular work for all purposes, to enable it to focus light from far as well as from near objects. Such an eye is never at rest during waking hours. As nature abhors a vacuum, so badly-shaped eyes may be said to abhor badly-defined pictures on the retina. An effort is made involuntarily by the flat eye to sharpen outlines and perfect the focus. This is always a muscular effort. When required for distant vision, as is always the case with flat eyes, some of the muscular force of the eye is used up, leaving less for the accommodating power in viewing small near objects. If the eye be very flat and the demand upon the muscular apparatus necessarily very great for even distant objects, then the moderate use of the eyes for reading soon exhausts the remaing muscular power. After reading for a short time, the natural relaxation of the over-worked and tired muscles changes the focus of the lens, blurs the image upon the retina, and causes the letters to run together. A little rest enables the muscles to resume work and the printed page to be again clearly seen, but a very few more minutes' use of the tired muscles again blurs the page. If the effort to read be persisted in, pain in the eyes and in the head ensues. If the muscular force be weakened by any acute disease, then the eyes give out the sooner. We experience this in children after measles, diphtheria, etc. Children who could study with comfort before the attack, find themselves unable to read for any length of time afterwards. Often months are required before the eye muscles again become strong.

An eye may be so very short in its anterior-posterior diameter that all the intra-ocular muscular power is required for viewing distant objects, leaving none for near work. Children with such badly-shaped eyes can not study, because from deficiency in the focusing power of the crystalline lens they can not distinguish the shape of the small letters. The nervous apparatus of such an eye is good. The retina and optic nerve are perfect, but the picture thrown upon this retinal screen is blurred, solely for want of accurate focusing power. Add to the lens power, and perfect vision for small objects is at once obtained. The accidental use of their grandmother's glasses to aid the crystalline lens to focus a sharply defined image is a marvellous revelation to such an eye, and shows just what it requires to make it a strong, useful organ; viz., a pair of properly adjusted magnifying spectacles. With such scientific aid the child is in condition to undertake hard study, and seeing clearly becomes easy. Because over-exertion of the eye muscles is no longer required when the child wears properly selected glasses, no more pain in eyes and head is experienced during study hours.

Although rest from near work will always bring about relief from the pain consequent to over muscular exertion, the advice so often given to parents by the family physician, to take hyperopic children from school, and let them rest their eyes from study, for months at a time, is bad, because it is founded on ignorance of the cause producing the trouble. At the end of six or twelve months the eye is just as misshaped as it was before the rest was taken, and application for near work will surely bring back the former painful discomfort. This is a matter of every-day observation. Adjust proper glasses, correct the error of refraction, give the eye muscles less work to do by allowing the eye to do its work with spectacles on, and consequently without effort, is surely the rational course to be pursued. *With the aid of magnifying glasses for all uses, a flat eye will need no rest. To rest such eyes with the expectation that they will become strong is delusive, and is therefore bad advice.*

Again, an eye may be misshapen from the round standard by being longer than it ought to be. An eye long in its antero-posterior diameter is more oval than round, and is called near-sighted or *myopic*, because it only

sees near objects clearly. The retina is so far from the lens in long eyes that a focus of light from distant objects is made before the retinal screen is reached. When the picture is finally thrown upon the nerve layer it is ill defined, and consequently blurred. Distant objects for such eyes are always befogged, unless the strength of the crystalline lens is weakened and its focus lengthened by the use of concave or near-sighted glasses. As flat eyes were always congenital, so long eyes may be found at birth. As a rule, however, eyes acquire this condition, and become misshapen by too much study in early school life. When an eye, previously good for seeing distant objects, changes shape and becomes near-sighted, the change indicates a yielding of the sclerotic or outer tough coat which is the sustaining wall of the eye-ball. This is a weakening and diseased condition of the organ, which will eventually be a serious injury if it becomes excessive.

When progressive near-sightedness is found in school children, in order to check the rapid deterioration in this very valuable organ, rest from eye work becomes a very important factor in the treatment. When the eye-ball is elongated, the cornea retaining its regular outlines, concave spherical glasses correct the defect in the focusing power of the lens and make vision better; but this aid for distant vision does not make such young and still growing eyes strong or capable of standing abusive work.

There is still a very important class of misshapen eyes, also starting usually with the very beginning of life. *It is to call attention to the headaches and eye pains caused by many such eyes that this paper is written.* In this large class of painful eyes the cause of trouble lies in irregularities of curvature of the surface of the cornea. The curvatures of the various meridians differ, as if the eye-ball had b en flattened from its sides. In such eyes the misshapen cornea may be represented by the crystal of a watch, which has lost its true spherical form, from irregu lar pressure upon its edges when the substance of the glass was still soft. The curvatures of the short diameter, corresponding to the direction of pressure, must be greater than those of the longer ones, and this must necessarily vary the focus of light passing through these different convex surfaces. In some meridians light may pass through and focus correctly upon the retina; in other directions the focus of transmitted light will be made too rapidly or too tardily, in either case blurring the retinal image, and causing defective vision. Whether the cornea border be compressed vertically, horizontally, or obliquely, it so changes the surface of the cornea for that direction, that however perfectly the other surfaces of the cornea may focus, the faulty curvature acts as if it were a distinct lens of different focal power, and it will cast shadows over the sharply defined picture made by the correct portions of the cornea. This error of refraction is called *astigmatism*, and may be found in long, short, or round eyes; hence we find simple or mixed hyperopic or myopic astigmatism. Such irregular corneas are frequently met with. In all such eyes an effort is made automatically to correct this fault by changing the shape of the crystalline lens to correspond with the irregularities in the cornea. Fortunately the lens in young persons is so soft and jelly-like that very little action on the part of the eye muscles corrects the faulty lines of refraction, and a perfect focus is secured. For a time this succeeds well, and comfortable clear vision is enjoyed, provided the application of the eyes for near work is not too long continued. But unfortunately the lens is hardening steadily with advancing age, and the muscular effort has to be continually increased till it becomes irksome and finally painful. The discomfort produced does not restrict itself to the eyes alone, but diffuses itself over the brow, forehead, and temples, causing headache more or less persistent. In some cases the pain invades the whole head, back of neck, and even spine. These headaches can always be brought on by eye use. To some very sensitive astigmatic patients eye use refers to their whole waking life. They arise in the morning with comfortable heads, but before they are dressed the headache has been started by the necessary toilet preparations, and it increases in severity with the advancing day. Sunrise and all day headaches they are, with some of these very susceptible persons, whose eyes see differently for the different curvatures of their cornea.

Every object in nature will radiate light from every exposed surface, and the eye catches some of these rays. Where the cornea is regularly curved, light from any and all directions is accurately focused on the retina, and while we see every thing perfectly we are not aware that we have eyes, so painlessly do they functionate. To the abnormally sensitive astigmatic eye this varied direction of light beams, transmitted through and irregularly refracted by the varied curvatures of the cornea, necessitates nearly

a choreic action of the ciliary muscles. From this perpetual changing of focus, now for one part of the cornea and then for another, fatigue of the muscles and pain in the eyes must soon be induced, even to the extent of making sunlight annoying.

This irregular shape of the cornea can be detected if the eye views a drawing similar to a clock dial, traversed by groups of black radiating lines of equal size and distinctness. By a well formed eye these groups of lines are seen with equal sharpness of outline and of the same degree of blackness. By an astigmatic eye some of these groups of lines are brought out much more boldly than others. While some remain black, others of these black lines may appear gray, and at times even red or blue; and instead of standing out boldly in the group, they run together as if they were one solid line. The faulty lines are always at right angles to those most closely seen. With the clock dial card, if the lines running from 12 to 6 o'clock are brightest, those from 3 to 9 o'clock will be most blurred. If those from 10 to 4 are the most clearly defined, the blurred lines will be in the direction of 1 to 7 o'clock, and so on for any other series of lines. If a cylinder lens be selected, which will make the dull lines as bright as the clear ones, this peculiar eye-glass, when carefully set at the proper angle, will equalize vision, and will remove the discomfort which the use of the eyes had formerly produced.

The ordinary spectacles. worn by the masses, are called spherical lenses, being sections of a sphere or ball. Such are the glasses worn by near-sighted and by old persons. The peculiar glasses which correct irregularities of corneal refraction are called cylinder lenses, because they represent a slice of glass taken from the length of a round bar or cylinder. The spherical and cylinder glasses bear the same relation to each other as would an open umbrella to a wagon top. The cylinder lens has, as it were, a ridge pole over which the curvatures of the lens are made, while the spherical lens curves in all directions from a central point. In the use of cylinder glasses the ridge pole or plain surface is always set in the direction corresponding to the clearest lines of the clock dial, and the curved surfaces of the lens are put necessarily in the direction of the blurred or discolored lines of the dial. Such cylinder glasses alone can give rest to the weary muscles in astigmatic eyes, for without them these irregularly curved eyes cannot secure rest except during sleep.

A very useful law can be laid down for the guidance of physicians in the treatment of their eye complaining patients, viz., that headaches which come on with the use of the eyes, and which disappear during the rest which a night's sleep brings to the weary eyes, do not usually depend upon gastric, hepatic, cerebral, or uterine troubles, as is so commonly believed.

When school girls from 12 to 18 years of age complain of eyes and head aching, after hours of close application, and are not annoyed in this way during vacations or times of eye rest, inquiry is yet made by the family physician concerning the menstrual functions. Any tardiness in the appearance of this discharge, or any deviation in its amount or frequency from what the physician has established in his own mind as the normal, is deemed too often a sufficient and satisfactory explanation for all the head and eye discomforts. According to their theory, when the monthly discharge becomes regular the head and eye troubles will disappear; but permanent relief does not come as was expected. When young men complain of these identical symptoms of eye pains and headache after hours of study, I sometimes wonder why, from professional habit, their menstrual functions should not be also inquired about, for the same explanation might as truthfully be accepted for them.

In this connection I will also say that these eye headaches, disappearing after sleep, have their origin neither in malaria nor in a bilious derangement, notwithstanding the fact that these terms are used every day in connection with them by patients and physicians. Neither quinine, calomel, morphine, nor pessaries will prevent this kind of eye headache, although building up the system in feeble persons will help the eye muscles and relieve them. The careful adjustment of proper glasses, by correcting the painful muscular effort, alone will cure them. Rest is a very frequent prescription with physicians for such painful eyes. It will quiet temporarily the pain, but what permanent good can it possibly secure? When upon the use of the eyes the head aches, and when painless heads are made painful by reading, with very few exceptions, it is the abnormal curvature of the cornea which causes the eye and head pains. How can rest bring about a correction in these faulty curvatures? Might as well expect rest from walking to make a shortened leg grow to the length of the other, as to expect a shorter curve in one direction of the cornea to grow out to the dimensions of the other longer meridians by

resting the eyes from reading or sewing. We can readily see the absurdity in the leg suggestion, and yet many physicians do not see that the expectation from the eye rest is equally preposterous.

How many thousands in this country to-day are impatiently and uselessly resting eyes that pain when put to near work, when a pair of properly adjusted spectacles will correct the evil?

Nearly every day I restore some restless patient to his work who had sought in vain relief from eye pains in rest; or I assist some ambitious person, who having acquired an enviable start in life, feels that his painful eyes have become barriers to further study and prospective promotion. Daily, by the use of properly selected glasses, I cure headaches, often of years' duration, and which have resisted every species of medication. In so doing I have often been able to satisfy anxious patients that their brains, stomachs, livers, kidneys, or uteri, have been accused wrongfully of producing the headaches, and that these have ever been innocent and healthy organs. The following remarks I have frequently heard from patients to whom I had recently prescribed astigmatic glasses: "For one week, ever since I put on the spectacles, I have been free from headache, and it is a freedom that I have not had before for years."

Although most astigmatic eyes cause headache and eye pains, if the eyes are much used in fine work, especially by artificial light, I find cases of faulty refraction from astigmatism in which headache is not and has never been an annoying symptom.

In some astigmatic persons a strong muscular development enables them to conceal the corneal irregularity. Should any disturbance of the system temporarily weaken this muscular power, the eye muscles, along with the other muscles of the body, are weakened and unable to keep up their work; then are pains induced. If it be a bilious or gastric disturbance, its temporary influence over the muscles is mistaken for the actual cause of the headache, when it is only the indirect cause, permitting the latent trouble to become manifest. If the astigmatism did not exist in a concealed form, there would be no headache on use of the eyes during these general disturbances.

Again, in nervous persons, especially in females, I have found great suffering about the head and eyes, clearly traceable to a small degree of irregular refraction, and promptly corrected by the constant use of carefully adjusted cylinder lenses.

The case with a report of which I will close this paper is one of unusual severity in effects, although a high degree of astigmatism did not exist. Such extreme discomfort as this lady suffered is fortunately not often found. The case is also peculiar from the length of time that she suffered before her eyes were suspected of being the source of the trouble. In this age of diffusion of medical knowledge by means of many medical journals, physicians are on the alert to distinguish eye headaches from the headaches caused by other organic disturbances, and usually at an early day invoke the aid of the specialist in eye diseases to remedy the evil. In her own case several years elapsed in testing newspaper remedies for headache, having lost faith in physicians from her earlier medical experiences. The case, however, will illustrate the efficacy of proper glasses in relieving even years of suffering.

Mrs. F., aged 38, the mother of several children, has been a martyr to headaches since childhood; and during the past thirteen years, since her married life, has been often nearly crazy from them. Any close eye work, continued for even a short time, would send her to bed with a raging headache. On an average she has spent one day out of every week in a dark room, and that has been kept up for months at a time. If she felt bright and applied herself to complete any needle-work, so necessary with a growing family, she never failed to pay the penalty in severe head and eye suffering. When she came first to my office, she frankly told me that she had come because she had been advised, not that she expected any benefit, for she had no faith in any curative agent whatever, having years since exhausted them all without finding any relief. She gave me this very clear history of her case: "Dr. A. has always been my family physician, and in him I have every confidence. Having in my early married life exhausted his skill in vain attempts at relieving me of suffering, he gave up treating me for these headaches many years ago. Under his advice I had consulted Prof. B.; you know him to be one of our leading practitioners. He acknowledged that I had a good family doctor, but thought that something might have been overlooked, and he hoped to find me a remedy. He varied his medicines, as one after another failed to procure me relief, and finally he advised a visit to the sea-shore. I spent six weeks at Cape May, and while there rested my eyes from all work, eschewing both reading and sewing. I returned home with body invigorated by the salt

baths, and was free from pain. As soon as I commenced using my eyes in sewing all the old distressing symptoms returned. My family physician and friend, seeing me in some of these terrible attacks, advised me to consult another physician, Prof. C., who you know has the reputation of being a very skillful physician. He had me under his professional care all winter and spring. Summer found me no better. Any use of the eyes in sewing or reading sent me to bed with twenty-four hours of suffering before me. He finally advised a course of mineral waters, and sent me to the White Sulphur Springs of Virginia. There I spent two months, which improved me much in health. In the fall I returned to Baltimore, looking and feeling well. A very few days of housekeeping showed me that the long rest at the springs and the drinking of sulphur waters had brought me no permanent good. My head at times ached as badly as ever.

"I now despaired of ever getting relief, because I had sought the best medical advice at my command and all to no purpose. Some of my friends, in their anxiety to see me cured of the daily suffering, advised me to try homœopathy. I accepted the suggestion, and sent for Dr. D———. He examined carefully into my case, and said that he could cure me. With these assurances from the new physician, my feeling barometer at once went up, and my future prospects brightened. I entered actively into the course of medication mapped out by him. I took his mixtures hour by hour, for days and weeks, my faith growing unfortunately less and less with the monotony of the dosing. Finally, as my headaches were not mitigated even by the long-continued treatment, I gave up all hope, and dismissed the homœopathic physician.

"I felt that my case was now beyond medical cure, and I became despondent and rash. In my anxiety to secure relief I have tried anything that any one would suggest. I believe that during the last six years I have taken every quack remedy warranted to cure headaches that I could hear of, as published in the newspapers, and my many friends have kept me well supplied with this kind of information. Recently I have heard how Miss E——— has been cured of constant headaches by wearing glasses, and my friends have suggested that I have my eyes examined. On the principle that, in my desire to escape this bodily torment, I have been willing to try every treatment that has been brought to my notice, I have come to have you examine my painful eyes; but I must tell you candidly that I expect no benefit, and have given up all hope of obtaining relief."

Upon examination, I found that she could read the finest print, but only for a few lines. Her distant vision was also acute. Fixing the eyes upon the clock dial trial card for a short time caused pain in the head and eyes, and also induced a feeling of nausea. I found that she could clearly see the vertical lines of the test card, but only dimly those which were horizontally placed. I selected from the trial case a magnifying lens which would make these blurred lines perfectly clear for each eye, and finding the corresponding cylinders, adjusted them at the proper angle in a trial frame. These I placed before her eyes. To her surprise, not only did all the lines come out with equal boldness of color and of definition, but she found herself able to stare at them without inconvenience. After she had worn the glasses for some minutes, feeling great comfort from them, I removed the frames, when immediately the nausea previously experienced came on. The restoration of the glasses brought back strength of vision and comfort. I prescribed for her the proper cylinder lenses set at an angle of 180° in spectacle frames, to be constantly worn. So anxious was she to test these spectacles that on her way home from my office she called at the optician's and remained in the store while the glasses were being fitted to the frames which she had selected. When they were ready she put them on at once and sallied forth. Before getting home she found herself walking with a degree of comfort which she had not known for months.

The rapid improvement commenced from that hour. Her headache disappeared within three weeks by the rest which her eyes enjoyed from the constant wearing of the spectacles. Now she makes her eyes do just what she pleases. Her constant headaches are bygones, and are only remembered from the years of torture through which she had passed. Her face has become bright and free from care as her head is free from pains. Her relief by such apparently simple means, and without medicines, is called a miracle by herself, and is a marvel to her friends. No amount of rest without these cylinder glasses could have effected this cure from suffering. It had been thoroughly tested, and had been found as useless as the many prescriptions with which during many years her body had been drugged. *Cylinder glasses alone could, and they have cured her.*

TREATMENT OF CHOREA.

BY JAMES E. FREE, M. D.,

Of Emporium, Pa.

When I was a boy thirteen years old I had an attack of chorea, which commenced in March and lasted until September. During the preceding fall I had been troubled with rheumatism, and from the date of a polyarthritis, accompanied with heart complication, I was more or less inclined to disorder of the nervous system. But it was the beginning of spring before I left school to undergo special treatment.

There were at the time two cases of chorea in the neighborhood, and it was the opinion of some that I had acquired the disease by either contagion or imitation. The suspicion was unfounded, because it is a fact demonstrated by experience that association (which did not take place) cannot produce chorea, and as a special germ has not been discovered in the blood with the microscope, there is no proof of contagion. The cause in the other cases was undoubtedly sexual indulgence; the female, who was one of the subjects, gave birth to an illegitimate child at the age of sixteen about two years afterwards.

Several plans of treatment were tried unsuccessfully, and as a last resort, I was placed on a farm and allowed to run wild. My experience there taught me something about chorea which I have ever since regarded as indispensable in its treatment.

The first thing that struck me as being necessary in my case was freedom from observation. When satisfied that nobody was watching me I had much greater control over the muscles of voluntary motion than at other times. I could take a glass of water at a certain spring without much inconvenience, but at the table I was liable to make the most awkward and fantastic motions. The reason for the increased difficulty when in the presence of others was my morbid sensibility, and the tension of an effort to appear unconscious of observation brought on a second stage of relaxation and motor excitement. Sustained mental activity was impossible; some of my attempts at writing are still preserved. The letters of an occasional word are fairly well formed, although the greater portion appear to have been constructed by a hand which did not know in what direction it would move next. Sitting still was absolute torture in the presence of others; if alone, I could sit down in a chair and be comparatively quiet; but the moment a footstep was heard, I was completely unstrung, and would be compelled to vibrate like a toy suspended by a piece of rubber. The will had lost the power to exact obedience from the muscular system; trying to do anything that required complex motion, or the effort to sit still, would cause chilly sensations to fly over me, my skin would itch, and there would be creeping feelings and subsultus and tic. And like a chill, these sensations would be followed by a stage of excitement; my pulse would run up high and become irregular; my heart would not pulsate synchronously with the radial artery, and respiration would not be rhythmical, and my legs and arms and head would fly off at a tangent.

Another thing which I found to be useful was a support for the back. The recumbent position abolished the muscular tremor to a marked degree, and after a night's rest there was absence of symptoms until attempts at coördination brought them back.

Sometimes when worn out by a hard day's work, if compelled to watch by the side of a patient, I feel the same restlessness. Every physician knows that nameless longing to stretch and yawn, accompanied with tingling and pricking sensations, which overtake the weary watches during his vigils; they are the same the choreic patient experiences. Another peculiar sensation in my case was connected with the larger blood-vessels. I can compare it to nothing better than the emptying of a bottle of water. The way the water escapes reminds me of the sudden emptying of blood out of an artery; and although not distinctly audible, I imagined that the sounds of the two actions resembled each other.

From what I experienced, I think the circulatory apparatus is the seat of the trouble. I had an attack of rheumatism previously, and there was implication of the cardiac structures, and that fact may be sufficient to account for the irritation of nerve-centres by molecular particles of fibrin set free from an inflamed endocardium. Hughlings Jackson claims that in chorea there is a minute embolism of vessels in the convolutions near the corpus striatum; that portion of the striatum, as the anatomist knows, is supplied with blood by the branches of the middle cerebral artery, and interference with its nutrition would account in some measure at least for the muscular instability.

There are numerous causes for chorea; thus tenia, a fœtus, masturbation, etc., may serve as samples. By some writers fright has been placed at the head of the list, but

how it can produce the effects which morbid anatomy proves to exist, is an unsettled question. Masturbation is a cause the frequency of which is hard to estimate, because the secret is almost sure to be concealed with great cunning as long as possible; however, genital congestion is a frequent post-mortem appearance. The situation in a case of chorea seems to be this: there has been an exhausting drain upon the nervous system, the centres which control the circulatory function are not supplied with their normal food, and consequently deterioration of tissue results.

In the REPORTER recently a contributor commends to the notice of the profession cimicifuga as the tonic par excellence in this disease, and says that it is used much less than it ought to be. One reason for its want of popularity may be its nauseous taste.

I remember that its use was recommended in my case, but owing to its constant rejection by the stomach, it had to be discontinued. There is no other drug in the materia medica that has a similar effect upon me, but it is utterly impossible to keep snake-root in my stomach. Another writer observes that arsenic is the main reliance of practitioners in chorea. If it is true, it is unfortunate, for it does not deserve to be.

Thorough oxygenation of the blood always made me bright and hopeful, and I soon learned that the close atmosphere of a house aggravated the disease, while outdoor exercise, and especially expansion of the chest, produced a tonic effect. The cause of the morbid manifestation settles the question of the applicability of arsenic. A friend of mine, who practices in a malarious district, extols the following:

℞. Strychnia sulph.,
Acid arsenious, āā gr. j.
Hydrarg. bichlor., gr. ij.
Quinia sulph., ʒj.
Gentian q. s. ft. pil. No. xxx.
One pill to be taken three times a day.

Cases of chorea that do not show a tendency to recovery when their surroundings are favorable should if possible be placed in a secluded spot where freedom from observation and plenty of fresh air can be obtained. Those who have not realized the morbid sensibility of choreic patients cannot appreciate the necessity for withdrawing them from the contact of society, and also the foolishness and futility of attempts to overcome that feeling of timidity by such devices as are common in dealing with hysteria.

Every morning the patient should have a nourishing breakfast, and afterwards a bath and thorough rubbing. "Suppose the patient will not eat?" you say. Yes, but he will eat when once he begins to feel properly oxygenated blood coursing through his body, unless his disability is so great as to interfere with mastication and deglutition. If he refuses food, there is probably some disorder of function that can be reached by means of our art. The problem is to obtain the best substitute possible for nature while we encourage and educate the sluggish faculties to resume their sway.

Bathing and rubbing are important. Chorea is a disease that makes the surface of the body uncomfortable. Subsultus is common, and a bath in water of a comfortable temperature, in a comfortable apartment, to be followed by rubbing with dry towels, brings the blood to the surface, and causes a grateful sensation of ease instead of the itching, uneasy feeling.

After the bath some method of gentle exercise should be practiced. What is indicated is something to cause a shaking-up of the entire system. Nothing violent should be tried. Motion, such as is obtained by moving down stairs, will suit patients who are large and intelligent enough to practice it. A regular lesson in calisthenics is not desirable; neither are dumb-bells and Indian-clubs, because to obtain the supposed benefit a certain power of concentration of the mental faculty is demanded when perfect abandon is the desideratum. Executing a dance is good—not the intricate parlor figures, but only the jumping, up and down motion—by which, especially, the muscles of the extremities are thoroughly used, and the entire body shaken. The greatest caution is necessary in commencing these lessons, because to one unaccustomed to them only a few minutes' exercise is sufficient to cause stiffness and pain in the over-worked muscles, along with headache, nausea, etc., the following day.

I am in the habit of insisting upon a gradual increase in the amount of exercise. Beginning with a short lesson, say twenty to fifty jumps, the number is increased until two or three hundred is reached. This need not take more than ten minutes daily, and when once habituated to it, as the patient is likely to be in a short time, no interference with digestion need be feared. Instead of becoming irksome, these daily lessons are enjoyed, and I have several times had to restrict the number and amount of each.

IS CHLOROFORM MORE DANGEROUS TO ANIMAL LIFE THAN THE BROMIDE OF ETHYL?

BY LAURENCE TURNBULL, M. D.,
Of Philadelphia.

Dr. Laurence Turnbull read a paper at the conversational meeting of Philadelphia County Medical Society, December 22, 1886, containing a series of experiments by Drs. Turnbull, E. J. Reichert, and Robert M. Thomas, to prove that chloroform is more fatal to animal life than bromide of ethyl or hydrobromic ether. He also gave a history of the so-called fatal cases attributed to bromide of ethyl, and proved by a careful study of each that the first two were the result of disease of the kidney and phthisis, and the last from not using the prop between the teeth and having no one at hand to use artificial respiration, and also using a mixture of the bromide of ethyl with something else, under a false name. The reader of the paper also alluded to the danger of a mixture of chloroform and nitrous oxide in London, France, and this country, and the death of one or more individuals whilst under its influence. He, in conjunction with his friends, had made a number of experiments on the sedative effect of chloroform upon the heart's action and the reflex phenomena, on irritation of the sensory filaments of the fifth nerve, thereby showing that a small dose of chloroform is much more dangerous than the bromide of ethyl, when the heart power is most seriously reduced by its action, and is incapable of supplying the brain properly, unless the patient is in the recumbent posture.

MEDICAL SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Reported by WILLIAM H. MORRISON, M. D.

Discussion on "Is Bromide of Ethyl as Dangerous to Life as Chloroform?"
(See above.)

Dr. James M. Barton in the chair.

Dr. William H. Pancoast: "I have had very little experience with bromide of ethyl, having used it but a few times. From my own experience, I would say that where an operation requires any length of time, ether is the most effective anæsthetic. My plan is to give ether without allowing the patient to be held, and if the patient becomes excited, to throw on the towel about a teaspoonful of chloroform, and after the stage of excitement has passed, to continue the use of ether. In office practice I use occasionally chloroform in slight operations, or nitrous oxide gas. When I employ chloroform, I direct the patient to hold up his hands, and the moment he begins to feel the effect of the anæsthetic, the hands will drop, and at that moment any slight operation may be performed. I am satisfied that when ether is given patients are often ether-logged. In many cases where death is attributed to shock, I think that it is due to the excessive use of ether. Ether and chloroform should not be mixed. The mixture of ether, chloroform, and alcohol is very dangerous. With such a mixture, you are giving chloroform without the precautions which chloroform requires. I have given ether in cases of phthisis and in cardiac disease, and in the last, have found the heart become steadier under its proper administration."

Dr. W. Joseph Hearn: "I have not had a large experience in the use of bromide of ethyl, but I believe that it must be watched as closely as chloroform. I believe that by the careful and gradual inhalation of chloroform, every case can be anæsthetized safely. In private practice I frequently use chloroform. I believe that there is less shock from its use than from ether. In cases where there has been great shock I have used chloroform with satisfactory results. Where a person is much debilitated, it does not require much of any anæsthetic to produce anæsthesia. I think that we can make no comparison between the effects of an anæsthetic on animals and on man. I have frequently given chloroform to dogs, although it has invariably resulted in death."

Dr. Laurence Turnbull: "With the utmost care, dogs can be put under the influence of chloroform, but if we are careless, in an instant the dog is dead. The late Dr. Griswold recently stated that ethyl bromide would kill dogs quicker than chloroform. This is not the case, as the observations in my paper will show. Dr. John B. Roberts has reported four deaths from the use of ether, where the fatal result was due to engorgement of the bronchii and paralysis. Ether is frequently continued much longer and in larger quantity in the lungs than there is any necessity for. This is especially true in regard to Squibb's ether, which contains very little water. In using this, it is well to moisten the sponge with warm water before applying the ether."

Dr. Laurence Turnbull exhibited a preparation of

Peroxide of Hydrogen,

which he stated was discovered in 1818, by Thénard, and introduced to the medical profession in 1858 by Dr. B. W. Richardson, of London. The first knowledge of its reintroduction into practical medicine was from a pamphlet received from a friend, Dr. Landolt,* of Paris, who employed it with success in ophthalmic practice, more especially in purulent ophthalmia and ophthalmia neonatorum. This was followed by experiments with it by R. J. Nunn, of Savannah,† in the treatment of diphtheria. Its use in ear diseases was first reported by Dr. Bethman in a paper read before the Chicago Medical Society, in February, 1885,‡ and then by W. A. Dayton, M. D., of New York, who was very eulogistic, stating "that the article has a future among the most trusted resources in the materia medica." Our experiments were made with it in 1886 in diseases of the ear.§

Hydrogen peroxide is a syrup-like liquid prepared when any of the peroxides are treated with an acid; the excess of oxygen is passed over to a portion of distilled water, and is converted into a solution of hydrogen peroxide. In this concentrated form it is stated to be a powerful vesicant and irritant; but in the solution in which we employ it, a twelve to fifteen vol., it is non-irritating as a rule, and yet it acts as a disinfectant and bleaching agent, destroying pus, blood, and all products of the disintegration of tissue. It acts by setting free the extra equivalent of oxygen, which attacking the septic material and disinfecting it.

In our detailed experiments|| we have found it useful in mastoid abscess, ulceration and caries of the ossicles, in acute and chronic suppurative inflammation of the middle ear. When applied warm it leaves a clean granulating surface, which is to be treated by powdered boracic acid and other gently stimulating and protecting agents, so as to facilitate the healing process of nature. When fresh it is neutral to litmus paper and has no odor. It should be kept covered and in a cool dark closet. If by any means any organic agent comes in contact with it, it is destroyed, and should not be employed. It resembles a solution of permanganate of potassium in all its actions, and yet a test of its purity is that it should dispel a weak solution of this agent. It is stated by chemists who make the preparation that there is an erroneous impression prevalent, regarding the difference between the percentage and volume solution, the latter often being mistaken for the former. The preparation which I obtained from Morgan, of this city, and made by Sheppard, of Boston, is a fifteen volume solution of about 3 to 3½ per cent.

The pure substance is 100 per cent. strong, and yields four hundred and seventy-five volumes of gas. A 1 per cent. solution then is equal to a 4.75 volume solution.

Owing to the article being unstable, it is stated that the preparations usually found in the market are acidulated with sulphuric acid. This free acid should be neutralized by adding baryta water, drop by drop, until a precipitate of the sulphate ceases to form, then filter or allow it to stand, and decant the clear liquid. The medicinal dose of the hydrogen peroxide is from one to three teaspoonfuls of the two-volume solution three times a day.

Dr. S. Solis Cohen: "I have had considerable experience with hydrogen dioxide during the last four years, and am willing to go further than Dr. Turnbull in regard to its value as a topical cleansing, disinfecting, and stimulating agent. It has a distinctly solvent effect on effete matters, such as devitalized epithelium. In a recent case of lingual psoriasis this effect was very marked. I have even thought I could notice a change in living but horny epithelium, though this particular observation is too recent to be positive. Its internal use, in conjunction with super-alimenation, greatly improves nutrition, especially in phthisis, anæmia, and wasting diseases generally. This I have attributed to the introduction of oxygen into the blood. It may, however, be due to a stimulating action on the digestive processes. The internal administration of the drug has been neglected in this country. The best form in which to administer it is that which is known as ozonic ether, introduced, of course, by Dr. Benjamin Ward Richardson, long ago. It is but very recently, however, that I have been able to secure a preparation of this, and then only by importing it from Robins, of London, Dr. Richardson's chemist, which I could have done in the first instance. This contains thirty volumes of the gas, while the aqueous solution contains but about ten volumes. The dose of ozonic ether is one drachm three or four times a day. It may be given undiluted or with some appropriate mixture. The aqueous solution must be given well diluted. One result of the administration of this drug in certain indi-

Aluminium Probe for Dilating the Nasal Duct.

Dr. Samuel Theobald showed a probe made for him by Charles Willms, of aluminium, for dilating the nasal duct. The special advantages were that it was very much lighter and somewhat stiffer than that made of pure silver, and the surface has a peculiar slipping quality, rendering its passage through the duct more easy than either the pure silver or nickle-plated probe. Although he uses styles very seldom, in exceptional cases he is obliged to, and finds the extreme lightness of those made of aluminium a very great advantage.

A Case of Squint.

Dr. Herbert Harlan related a case of squint in which the left eye turned downward. He cut the inferior rectus of that eye, and, as a result, very nearly corrected the deformity. He then cut the superior rectus of the other eye and thus got the two eyes on the same plane. At first the deformity was nearly as great as before, owing to the fact that the eyelids did not at once change their relative position to suit the respective eyes. This is being gradually accomplished, however, and he thinks that in a little while the edges of the eyelids will take their usual position in relation to the pupils. The case was complicated by a myopia of $-\frac{5}{D}$ in the right and a compound myopia astigmatism in the left. The left required a correcting lens of $-\frac{6}{D}=\frac{1}{D}$ eye 180°.

DISCUSSION.

Dr. Theobald had a case somewhat similar. When both eyes were used, there was binocular fixation, but if one eye was covered there was a movement of the other eye up or down, according to the eye examined. The condition was relieved by using prisms of only 1°, the base of one being downward and the other up. The patient, a boy of about 10 years, was very dependent upon his glasses.

Dr. A. Friedenwald had lately seen a case of downward squint in one eye, which, being congenital and combined with ptosis, he considered could not be cured by operation.

He had also seen a case of a lady who had a small vascular growth connected with the upper eyelid. He cut it off, but failed to check the hemorrhage with persulphate of iron or nitrate of silver, succeeding only with pressure applied for several days. He afterwards tried electrolysis, the immediate effect of which seemed to be to exaggerate the growth; but, after an interval of about three months, he found that the tumor had shrunk up very remarkably. He desired to call attention to the fact that electrolysis did not in all cases promptly destroy such growths.

Dr. R. Winslow had had electrolysis used for the removal of some small vascular growths on his own body; had found that there was a very decided amount of pain connected with the procedure. He thought its effect was due to its caustic action.

Dr. I. E. Atkinson said that electrolysis was effective in only a certain proportion of cases. Its action is not generally that of a caustic, as there is not enough heat generated to cause such action. He considered it the only reliable method for the removal of superfluous hairs. When it fails for this purpose, it is owing to the fact that the needle does not follow the course of the hair follicle. If properly used, it does not leave a scar. This much is seen only when the needle has to be repeatedly introduced into the same hole. The amount of pain experienced depends both upon the person and the manner in which it is used. The proper way is to introduce the needle attached to the negative pole, and then let the patient squeeze the sponge. When froth shows itself around the needle, the work is done. If the needle is withdrawn without breaking the current a shock is felt, otherwise none.

He had used electrolysis in certain other cases without success. In acne rosacea, introduction of the needle along the line of the blood-vessels will blanch the surface, but the vessels are not destroyed. He thinks excision of the vessels a better plan. Very small nævi can be removed successfully, but if large the operation has to be repeated so frequently as to be of no advantage. In the very small branching red spots, "spider cancers," so called, this method has been used by others with success.

If we set up a destructive action in parts of an area the pressure of the scar-tissue, so formed, may cause disappearance of the morbid growth. He thinks the electrolysis has no other action than that which is immediate.

Dr. Harlan had used electrolysis for the destruction of hairs. He thinks the degree of pain depends upon the situation of the hairs. Had found but little signs of pain when used upon the thicker portions of the skin, but considerable when the skin was thin and delicate, as about the eyelids.

Dr. Theobald had found that a single zinc-carbon cell, with electropion fluid, would raise a fine platinium wire to a white heat. He considers that a similar result would follow the use of a fine steel needle, and that the action is practically that of a galvano-cautery.

Dr. I. E. Atkinson considers that if the action was that of a caustic there would be an eschar formed. In electrolysis a froth is found and no eschar. He thinks that it has been demonstrated that it is a true electrolytic and not a caustic action.

Dr. R. Winslow said his experience was that it did form first a white and then a black eschar.

Dr. T. S. Latimer said he was skeptical regarding the ability of any one to follow, with a needle, the track of a fine hair. He thinks the effect is on the circulation in the immediate neighborhood of the hair follicle.

Dr. G. H. Rohé thinks the experience of dermatologists both here and abroad has clearly demonstrated that one can enter the hair follicle with a needle. He had done it with a needle, the point of which had been purposely broken off. There is no heat produced when a small quantity current is used. He had demonstrated this by holding the needle between his thumb and finger. It is a decomposing effect, as when both poles are placed in water. He believes that in vascular growths a change is brought about by which, although the growth does not immediately disappear, it gradually shrivels up. This may be brought about by an increase in the fibrous tissue. The same treatment has been successfully used in hypertrophic scars, a number of punctures being made in the line of the scar. It has also been successfully used in keloids.

Heart Displaced by Pleuritic Effusion.

Dr. William H. Norris exhibited a patient in whom the heart had been pushed completely over to the right side by effusion in left thoracic cavity, and held in that position by adhesions; the apex beat was below the right nipple. There was flatness over the region of the left lung. The patient, a lad of about nineteen, said the trouble had existed for some four years.

Dr. I. E. Atkinson doubted very much that the fluid had remained in the chest that length of time. The left pleural cavity was now evidently full of blood.

Several gentlemen recognized the patient as one who had been the round of the hospitals and dispensaries, but had always disappeared before any fluid could be drawn off.

Dr. W. T. Councilman read a paper entitled

Further Investigations on Blood in Malaria.

Dr. J. E. Atkinson said it had been his privilege to see some of Dr. Councilman's specimens, and to examine some of his cases. One patient, especially, demonstrated the value of microscopical examination of the blood in suspected cases of malarial poisoning. This man came from a malarious district and had suffered from chills, but there was no increase in the size of his spleen, and his liver was rather smaller than normal. Quinia had no effect to reduce the temperature, and the patient developed a hyperæsthetic condition about one of his shoulders. Examination of his blood failed to demonstrate any malarial organisms. A diagnosis of syphilis was made, the treatment changed to iodide of potash, and within twenty-four hours there was a very marked improvement in the condition of the patient.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated meeting, December 20, 1886.
Charles A. Leale, M. D., President.

The Pathology of Scarlatinal Nephritis.

Dr. F. Grauer read a paper with this title, in which he said that the forms of scarlatinal nephritis may be classified according to Friedlander into three varieties, the first being an initial catarrhal nephritis, the second the large flabby hæmorrhagic kidney, and the third acute glomerulo-nephritis, or nephritis post-scarlatinosa. The first variety occurs during the first week, is of short duration, and seldom causes death; the urine contains hyaline and mucous casts, rarely red and white corpuscles, renal, epithelial and granular casts. The second form occurs less frequently than the other two, and its time of invasion is from the first to the fourth week; its course is rapid; it is rarely attended by œdema. It is most likely to occur in the cases of scarlatina with marked angina, and diphtheritic inflammation. The tubules contain various forms of casts, de-

generated epithelium, increase in connective tissue. being a round-celled infiltration mainly about the Malpighian bodies and between the tubules; red blood-corpuscles are present. The kidneys are enlarged and soft, the cortical substance thickened, grayish-red, showing ecchymoses.

Nephritis post-scarlatinosa develops during the third and fourth weeks, œdema making its appearance when the patient seems to be convalescent. The urine is diminished in amount, is of high specific gravity, and contains albumen; also red and white blood corpuscles, renal epithelium, hyaline, blood, and granular casts. Fluid accumulates in the serous cavities; in some cases there is suppression of urine and death. The kidneys are enlarged, hyperæmic, the cortical substance slightly thickened, the glomeruli pale, and more or less enlarged. The tubules are normal; in some there is a slight parenchymatous change, the capillary loops dilated, filled with a mass of nuclei, being those of proliferated endothelial cells; swelling and proliferation of the glomerular epithelium. He thinks it is the proliferation and thickening of the endothelial cells which causes an obstruction to the circulation of blood through the capillaries, and not proliferation of the glomerular epithelium.

Laparotomy in Acute Peritonitis.

Dr. Joseph D. Bryant presented the vermiform appendix, the seat of three perforations, removed by laparotomy from a man about forty years of age, who had the symptoms of intestinal obstruction, severe pain, and great distension. The vermiform appendix was erect, looked like a distended leech, contained three perforations, two the size of a pea, and contained a small mass of soft fæces. It was tied at the base, removed, and the abdominal wound closed, antiseptic precautions being observed as far as possible under the circumstances. The surroundings and conditions were unfavorable, and the patient died.

NEW YORK ACADEMY OF MEDICINE.

Regular meeting, December 16, 1886. Abraham Jacobi, M. D., President, in the chair.

Fermentation, Putrefaction, and Suppuration.

Dr. Herman Knapp read the paper, which he had been led to prepare from the fact that there was a very wide difference of opinion among physicians as to the importance of bacteriology, some claiming that the great majority of all diseases were of bacterial origin, while others claimed the contrary, and that bacteriology was of interest only from a scientific and not from a practical point of view. Dr. Knapp quoted the statistics of mortality of several of the cities of the United States for a recent week, as reported in the *Boston Medical and Surgical Journal*, in which it was stated that the percentage of deaths from infectious diseases was thirty-three; yet this did not include the deaths from consumption, diphtheria, croup, diarrhœal affections, pneumonia, peritonitis, endocarditis, malaria, gonorrhœa, typhoid fever, skin diseases, and surgical affections. After a fair calculation, Dr. Knapp thought we were justified in drawing the conclusion, which at first surprised him, that of the total number of deaths ninety per cent. were from diseases of bacterial origin. The greatest practical advance which had been made in any department of medicine of recent years was to be seen in surgery, due to the introduction of antiseptic methods, or the prevention of suppuration, which he proceeded to show took place only through the agency of germs or bacteria.

Dr. Knapp presented some flasks in which he had repeated the experiments of Schultze, Schwam, and others, demonstrating the manner in which fermentation takes place. If germs were rigidly excluded from a fermentescible substance, fermentation would not occur; fermentation was the decomposition of corro-hydrates by the action of the yeast plant. He further showed that putrefaction is the splitting up of nitrogenous substances into simpler elements through the agency of germs, the germs, however, differing from those at work in the process of fermentation.

The author then proceeded to show that suppuration is also dependent upon the agency of bacteria, the substance acted upon being living nitrogenous matter, while in putrefaction the substance acted upon is dead nitrogenous matter. He asked: Does mere traumatism produce suppuration? Do foreign bodies produce suppuration? Do chemical agents of any nature produce suppuration? To each of these questions he gave a negative reply, based upon experimentation with rabbits. That traumatism would not produce suppuration was proven by operations upon the eyes of rabbits—upon one eye with a perfectly clean instrument, suppuration following in no case; upon the other eye with an infected instrument, suppuration following in every instance. Simple fracture would

never be attended by suppuration unless there was a suppurating point at some other part of the body, the germs being transported through the circulating medium.

To prove that foreign bodies would not cause suppuration, he had left the end of a rusty hair-pin brought to a glow (thus killing all germs) in the eye of a rabbit, and suppuration had not followed; the end of the same hair-pin not brought to a glow produced suppuration.

It was generally claimed, and by the highest authority, that chemical substances will produce suppuration. Dr. Knapp thought this was an erroneous belief due to the great difficulty of experimenting antiseptically with these agents. This was especially true of croton oil, which was extremely irritating in the smallest quantity. Yet he had been able to inject a drop of this substance into the eye of rabbits and not produce suppuration. Signs of irritation within the eye followed, but not suppuration, nor were germs present. In the other eye, however, precautions against the entrance of germs with the oil not being taken, suppuration ensued. The animals were shown.

Dr. Charles Heitzman made some remarks, and said that he had examined the eye of the rabbit into which croton oil had been injected with precautions against the entrance of germs, and while he saw signs of inflammation, he could find neither pus nor germs. Yet it seemed difficult to explain the development in a person otherwise healthy of, for instance, suppurative osteo-myelitis.

A Case of Fæcal Accumulation in the Rectum and Colon: Complete Obstruction of Bowels Supervening: Operation: Recovery.

Dr. Price Morris thus writes in the *Brit. Med. Jour.:*

During the month of August, 1877, I was consulted by a young lady, aged 24, who complained of symptoms of indigestion, occasional vomiting, etc., for which I prescribed. Finding, on passing her home about a week afterwards, that she was no better, I asked her to undress herself, so that I might properly examine her. To my great astonishment, I found that she had large, nodulated, firm, painless, movable tumors, occupying the lower part (and chiefly the left side) of the abdominal cavity. There was no gastric tenderness, menstruation had been regular, the bowels were being moved —in fact, there existed a kind of spurious diarrhœa. I considered it advisable at once to examine the rectum, when I found that this was tremendously distended, and packed full of dry, nodulated, earthy, fæcal matter, the anus being in a continual state of patency, due to the paralysis of the sphincter by mechanical distension. So much was the rectum distended, that a child at full period could easily have passed through it. Before going any further, I had better state that this individual, when a child, was in the Denbigh Infirmary, under the care, I believe, of Dr. Turnour, for accumulation in the bowels.

Getting the patient on the edge of the bed, covered with a sheet of oil-cloth, and using plenty of soaped warm water, I diligently dug away at this mass with my finger (which I think better and safer than a spoon) for a considerable length of time, finding that the mass was gradually descending as it was being removed below. Suffice it to say, that in this way the whole masses in the colon and rectum were cleared.

I cautioned the patient now about taking occasional aperients, and an enema to prevent a recurrence; but this she failed to do, so that after losing sight of her for about eighteen months, I was called to her again.

This time I found her just in the same state, applied the same treatment, but not with the same result, inasmuch as a mass was left in the sigmoid flexure of the colon, which would not descend into the pelvis. This could be felt by introducing a long tube, against which the point would impinge, but which would give way under a little pressure. Injections were of no avail, coming out as administered, owing to the compactness of the mass. After this attempt to clean the bowels, symptoms of complete obstruction supervened, as evidenced by her vomiting every meal she took, as well as a total stoppage of any fæcal discharge from the bowels.

These symptoms were not accompanied by any greater distension or tenderness of the abdomen, neither was there any additional

pain; and in spite of the administration of various kinds of purgatives and medicines, as well as enemas, they continued persistently for several weeks. The patient, in the meantime, was getting rapidly emaciated, so much so that, before long, death from starvation must take place.

At this critical period her parents asked me one day if I would have any objection for her to see a very eminent provincial surgeon, which, of course, I gladly consented to. I wrote a full history of the case for her to take with her, which the above gentleman kindly acknowledged, with the remark that it was a very extraordinary case, and that he had not made up his mind what to do. In a few days more I received another communication, stating that, upon further examination, he found that the case was beyond the reach of surgery, and recommending a trial of large doses of aloes. The patient returned home, and tried the above doses for a fortnight, but each dose came back.

Whilst she was away, an idea on one occasion suggested itself to my mind of doing something for her. The idea was to introduce my hand into the gut, and to push it up as far as possible, with the intention of getting at and removing the obstruction. After apprising her and her parents of this —stating that, if it was not successful, she would be left in the same state as at present —I operated, with the assistance of my old master, Dr. Davies, of Llanfair Talhaiarn, and Dr. Roberts. My intention was to dilate the anus; but, finding this impracticable, under chloroform, I divided the whole structures back to the coccyx. Now I could easily pass my hand; and Dr. Roberts passed a long tube in by my wrist, through which warm soaped water was injected. At the top of the pelvis I came across the big mass which I had so often felt and vainly attempted to remove, but now I could easily crush it. The arm was now withdrawn, when the whole was expelled. After reintroducing the arm, I found that the colon was in a very abnormal condition, because, instead of there being an ascending, transverse, and descending colon, it was one tremendously distended chamber, and with my whole arm introduced up to the axilla, I could, on account of her great emaciation, investigate and manipulate every part of the abdominal cavity, with the other hand externally. Strange to say, in the neighborhood of the right iliac fossa I found an opening of an oval shape, large enough to allow the passage of a good-sized plum (an inch and a half long), with a well-defined margin. This was plugged with a lump of hard fæcal matter, which was removed and crushed in the large amount of water which had by this time been injected. Every part was now thoroughly examined; and, after satisfying myself that there could be nothing more, the arm was withdrawn. Sutures were carefully inserted, a soft elastic catheter placed in the bladder, and by-and-by a large dose of opium given. Vomiting occurred next day, due, no doubt, to chloroform; after which she went on for a fortnight, fed upon liquid nourishment, without any vomiting. At the end of this time, I detected a doughy kind of swelling in the left iliac fossa, which, I thought, must be the result of what she had been eating; and in a few days more, upon removing the sutures and catheter from the bladder, fæcal matter was found in the rectum, which was all easily removed by an enema.

After this, she got up, gradually resumed her ordinary diet, and I took care to watch her carefully for some time, with the satisfaction to find that the bowels gradually resumed their normal functions without the use of aperients or enemas; the bowel, no doubt, as time went on, in spite of its extraordinary distension, resuming its tone and contractile power; whilst the inestimable advantage of a sphincter capable of discharging its functions has been regained. In this way the patient has kept for over seven years. Lastly, what the above opening was, unless it was the ileo-cæcal valve, I am at a loss to know.

A Case of Supposed Fracture of Neck of Scapula.

Dr. G. Y. Eales thus writes in the *Lancet:*

Last September R. B., aged fifteen, a spare, delicate-looking lad, came to me with an injury to the left shoulder. He was playing with several boys, butting at each other with folded arms, when he was knocked over and fell on his left shoulder. On examination I found the following points of observation:

1. Considerable bruising of the deltoid.
2. The acromion process prominent, with depression underneath, and outer third of the deltoid flattened.
3. Arm lengthened about an inch and a half, and drawn away slightly from the side.
4. A rough object high up in the axilla in the neighborhood of the neck of the scapula.
5. Humerus rotated freely and smoothly, and with but little pain.
6. A round projection in front and below the shoulder, which proved to be the head of the humerus on rotating that bone.
7. On raising this projection upwards,

outwards, and backwards, crepitus was produced; the contour of the shoulder was restored, with disappearance of the deformity.

8. Slight increase of vertical measurement around the joint.

9. Great freedom of passive motion, with but little pain.

Owing to the bruising, I was unable to manipulate the coracoid process; I therefore put the arm up with a pad in the axilla, with the elbow raised and bandaged to the chest. Five days afterwards, the bruising and swelling having partially subsided, I took off the bandages and found the same condition of things as when I first saw him, but much more plainly. On raising the head of the humerus all the symptoms disappeared, accompanied by loud bony crepitus audible to the bystander; and on removing the reduction force all the above-named symptoms again appeared. I was struck with the ease and comparative absence of pain with which the fracture could be reduced, also the readiness with which it became displaced on removing the reduction force. The rough object in the axilla was now more distinct, and disappeared on reducing the fracture, and was apparently the scapular neck. I now noticed also that the coracoid process did not appear to move on reducing the fracture.

Remarks.—The noteworthy features of the case were—

1. The ease with which the fracture could be reduced, together with the ensuing deformity on removing the reduction force.

2. The great freedom of passive motion.

3. The striking resemblance to dislocation into the axilla.

With regard to this latter, the lengthening of the arm, the freedom of passive motion, and the easy reduction of the deformity in the way I have mentioned were sufficient to exclude simple dislocation into the axilla. The other lesions which this injury simulates appear to be—

1. Dislocation of the humerus into the axilla, with fracture of its neck.

2. Separation of the epiphysis of the humerus.

3. Dislocation of the humerus into the axilla, with fracture of a portion of the glenoid cavity of the scapula.

The lengthening of the arm and the movement of the head of the humerus on rotation are against the first two. Holmes, in his "System of Surgery," states that it is the opinion of most modern writers on surgery that a simple fracture of the anatomical neck of the scapula never occurs, and that Malgaigne has shown that the symptoms of the supposed lesion are identical with those of dislocation of the humerus into the axilla, with fracture of a portion of the glenoid cavity of the scapula. In another place Holmes admits that the two lesions are indistinguishable during life. I hardly dare to express an opinion in the face of such high authority; but why should not a simple fracture of the anatomical neck of the scapula occur as readily as the more complicated injury?—because the force to produce either must be of the same nature and very considerable. It appears to me that the symptoms of this case are so analogous to those quoted by Dr. Lotzbeck, of Munich, and that recorded by Spence, and bearing in mind the fact of the coracoid process being apparently stationary, that I feel justified in saying that in all probability this was a case of fracture through the anatomical neck of the scapula.

The lad having passed from my care and observation for treatment by another surgeon, I am unable to give any details of the progress of the case, but I afterwards ascertained that he eventually gained very good use of the arm.

The Oculist, the Optician, and the Public.

Drs. L. Webster Fox and George M. Gould, of Philadelphia, thus write in the *Philadelphia Medical Times* for December 25, 1886:

It has in all civilized countries been found not only conducive to the public good, but also necessary to the public welfare, to limit the traffic in drugs to such persons as have pursued a special course of study, fitting them to dispense the materia medica intelligently, and who are in other respects qualified to deal wisely in matters which are of so highly important and delicate a character.

It is our conviction that the business of supplying the community with spectacles is, in its way, and to a degree, a function of as profound importance to the community at large; that at present this office is shamelessly prostituted to money-making; and that similar legal restrictions should be set about it as have been found beneficial in the case of drug-selling. Our contention is that the optician should be placed on precisely the same legal standing as the druggist; that is, he should by education, both general and technical, and by the restriction of his duty to his legitimate function, be placed before the community with a guarantee by the proper authority that he is qualified to do

what he pretends to do, and that he shall not pretend to do what is wholly beyond and outside his province.

Just as the druggist *quâ* druggist is not a physician, so should the optician not pretend by his practice to be an oculist. If the professions of medicine and pharmacy are distinct, it is beyond all cavil that the profession of ophthalmology is quite as different from that of manufacturing and selling optical instruments.

We speak thus strongly because the reason for the faith that is in us is derived from the memory of a long series of cases where irreparable injury and years of suffering have been the result of the common foolish habit of sufferers from eye troubles relying on the optician—respectable or quack—to do the work they should have been legally protected from seeking or getting, or, yet more correctly, from being deceived in the getting.

We had intended citing a number of our own cases in detail, but are warned that our limited space forbids, and we must with regret omit them. We cannot leave the subject, however, without referring to a recent case. It was that of a lady past 55, who relied on the optician to fit her with "old age" spectacles. Her dimness of vision, however, was only temporarily benefited by the spectacles, and they were soon changed by the obliging dealer. But there was before long a dimness of vision, and again a change. Finally, after many changes—we forget how many—and when the precious time of possible relief had been wasted, the patient came under observation with a typical glaucoma chronica, wholly beyond cure. No astigmatic correction had been added to the presbyopic glasses; and, if not absolutely induced, it is far more than probable that the glaucoma had been increased and its progress hastened by the irritation resulting from the glasses. At least, and this is the most important, the patient's reliance on the optician cost her the terrible penalty. Had the law directed her to a physician, as it does in other forms of illness, no such result would have taken place. No optician ever thinks for a moment of any but refractive errors, and, of course, not of the remote bearings of a supposed correction of these. Indeed, it may be added that perhaps many oculists are far from properly appreciating the persistently intimate co-relations of the errors of refraction (with their correction) and general ocular and cerebral disorders. So that it is no exaggeration to say that in writing a prescription for glasses, the judgment must be guided by a multitude of considerations that only the physician plus the ophthalmologist can for a moment be supposed to consider and estimate aright. How far soever from perfection the oculist may be critically adjudged, there can be no question that the peddler, the jeweler, and often the optician, are yet farther from it, and that some legal process of culling and gleaning in this field would be a great benefit to the community.

Puerperal Eclampsia Treated with Pilocarpine.

Dr. T. Coke Squance thus writes in the *Lancet:*

Early on the morning of Septemper 8 I was called to attend Mrs. L——, aged twenty-two, in her first confinement, her ordinary medical attendant being from home. I was informed that the "pains were slow," that she had been very sick, and complained of severe "pain in the head." On examination, I found the os well dilated, head presenting, and membranes (which were very tough) unruptured. I ruptured the membranes and applied a binder, but after waiting for some time the pains became very feeble, and the patient showed such signs of exhaustion that I proceeded to deliver her with the forceps, subsequently removing the placenta, which was partially adherent. There was no hemorrhage worth speaking of, and half an hour after the patient expressed herself as "feeling well." Her pulse when I left her was 72. Later on, I received a message to the effect that she was "going from one fit into another." On my arrival I found her quite unconscious, face flushed, pupils widely dilated, skin harsh and dry, abdomen tympanitic, bladder empty, feet œdematous, pulse 120 and full, and temperature 100°. Her friends informed me that she had had about a dozen exceedingly severe fits, during some of which they thought she was dead. During the "fits" she had passed fæces and urine. As an attack was evidently just commencing, I gave her a hypodermic injection of pilocarpine (¼ grain). The head was then being turned from side to side, the eyelids and eyeballs were moving rapidly, the mouth was drawn up towards the right ear, and the head turned towards the right shoulder, the countenance being of a livid hue. The fingers and thumbs were then flexed on the hands, the latter being strongly flexed on the arms, which were also somewhat flexed; the trunk and legs became rigid. The left leg was raised from the bed, and remained extended for fifteen seconds. There was a peculiar hissing sound on res-

piration, with convulsive movements of the larynx, the face becoming blue-black in color, and the patient seemingly on the verge of suffocation. The rigidity, which lasted for fifteen seconds, was followed by clonic convulsions, the face was frightfully distorted, and large quantities of frothy foam, slightly tinged with blood, came from the mouth. Respiration became restored and the convulsion ceased, with the exception of a little twitching, at the end of three minutes, by which time the patient was in a profuse perspiration. The attendant told me that this attack was barely half the duration of the previous ones. There was no further seizure until shortly before I saw her the next morning, when there was a slight attack. I repeated the pilocarpine then and once subsequently, and no further seizures occurred. She remained unconscious for three days, during which time urine was passed in large quantities. There was an abundant secretion of milk. When I terminated my attendance at the end of a week, her own medical attendant having returned home, she was making most favorable progress. In addition to the pilocarpine, I ordered her a mixture containing chloral hydrate and bromide of potassium, and pessaries of eucalyptus and perchloride of mercury per vaginam.

On Some Forms of Albuminuria Not Dangerous to Life.

The gravity of albuminuria, as a symptom, has been differently estimated at different times, but gradually it has come, in recent years, to be known that albumen often appears in the urine, even in considerable quantity and very persistently, in persons free from important organic malady. Indeed, it may be maintained that some patients with persistent albuminuria are yet eligible to life insurance at little, if at all, above ordinary rates.

It is, therefore, important to know the characteristic features of these non-dangerous albuminurias.

Dr. Grainger Stewart, in the January issue of *The American Journal of Medical Sciences*, studies the following varieties:

1. Paroxysmal albuminuria.
2. Dietetic albuminuria.
3. Albuminuria from muscular exertion; and,
4. Simplè persistent albuminuria; and illustrates each with reports of cases which are markedly characteristic.

The diagnostic features of paroxysmal albuminuria are the sudden and copious occurrence of albumen in the urine with numerous casts, the process lasting only a short time and occurring at intervals with or without a perceptible exciting cause. The exciting cause, according to Dr. Stewart, is irritation of the kidneys from blood-changes. The treatment should be directed, on the one hand, to the avoidance or diminution of renal irritation; and, on the other, to the regulation of the hepatic function, and of the chemical processes in the body. Happily, the attacks are usually of brief duration, and he has never known them prove permanently injurious.

Dietetic albuminuria is a variety which has long been more or less distinctly recognized. Some people suffer from it whenever they indulge in certain articles of diet. In some cases one kind of food, in others many, require to be proscribed; cheese, pastry, and eggs are among the more common offenders. Of this group our present knowledge does not suffice to afford a satisfactory explanation.

Those cases of *albuminuria following upon muscular exertion* Dr. Stewart is disposed to attribute to a general change in vascular activity. The prnicipal indications for their treatment are met by rest, judicious diet, and attention to the general health. Those remedies which act upon the muscular fibres of the vessels deserve trial.

The features of *simple persistent albuminuria* are the constant presence of albumen, usually in small quantity, unattended by tube-casts, diminution of urea, by increased muscular tension, cardiac hypertrophy, or other consequence of renal malady, persisting for a period of months or years, and little influenced by diet or exercise.

Dr. Stewart concludes his study with a consideration of the prognosis of these groups.

Intra-peritoneal Hemorrhage in a Newly-born Infant.

Before a recent meeting of an English medical society, Dr. Keser read notes of a case of intra-peritoneal hemorrhage in a newly-born infant of the male sex. The child was born at full term on April 29, and the labor was normal. The child was in a state of apparent asphyxia, but respiration was easily established. There was slight subconjunctival hemorrhage on the right side. On May 1 swelling of the scrotum was observed, and the penis was œdematous. On May 4 the scrotum was much more swollen. The temperature in the rectum

was 98°. The abdomen became swollen, and the lips were pale. The cord separated on that day without hemorrhage. The child died on the ninth day. There was an ecchymosis in the middle of the back. Melæna or hæmatemesis was not observed. The spleen was enlarged, and measured 9 cm. in length, 5 cm. in breadth, and 2 cm. in thickness. The upper half was swollen and congested, and very dark from hemorrhage, which seemed to have come from a lesion that looked like an infarct. According to Birch-Hirschfeld, the size of the spleen in a child eight days old was 4 cm. by 3 cm. The peritoneal cavity was full of dark fluid blood, the amount escaping being about eight ounces. The splenic artery appeared to be normal, as well as the other branches of the aorta. There was no hemorrhage or infarct in any other organs. The mother had had eight pregnancies. The first child died at the age of eighteen days, but the cause of death was unknown. After this child five still-births occurred. The seventh child was born at full term, was nursed by the mother, and remained well until the end of the fourth week, when epistaxis set in, followed by hæmatemesis and melæna; large ecchymoses appeared on the trunk and limbs, and death ensued after a week's illness. The mother had no tendency to metrorrhagia or to any other form of hemorrhage. There was no hæmophilic history so far as could be obtained. Spontaneous rupture, as probably occurred in the case recorded, was very rare. Ritter, who collected 132 cases of hemorrhage in new-born children, had never observed it. Grandidier had observed intraperitoneal hemorrhage, but the source of the blood was not discovered. Steffen found a rent in the convex surface of a soft spleen in one case of intra-peritoneal hemorrhage. Billard found at the necropsy of a child six days old a large quantity of blood in the stomach and intestine, and an enlargement of the spleen, which was ruptured; there was but a tablespoonful of blood in the peritoneal cavity. Dr. Keser could not detect the source of embolism, but believed that there was an infarct in the spleen as the result of arterial obstruction. Dr. J. H. Morgan related a case of icterus neonatorum attended with severe hemorrhages, and due to congenital obliteration of bile ducts.

Gastric Ulcer.

Before the Clinical Society of London, Dr. Montagu Murray read a paper on a case of gastric ulcer with unusual complications. An anæmic girl, aged twenty-three, was admitted on February 15 with indefinite gastric symptoms. On the 16th, the temperature rose suddenly to 103.6° F., a sharp pain was experienced in the left side, and a pleuritic rub could be heard. On the 17th, the abdomen was found to be tender and swollen. During the 17th and 18th there was severe vomiting. Hæmatemesis began on the 19th. At first the blood was bright red, and the amount ten ounces, but subsequently the quantities were smaller and the color much darker. Patient rapidly became weaker, and died on the 22d. Vomiting ceased four hours before death. At the post-mortem, acute left pleurisy and acute peritonitis were found. On opening the stomach, a small ulcer was seen at the cardiac end; its outline was roughly circular, its diameter an inch, its wall thickened and precipitous, and its floor composed of peritoneum, perforated in the centre by an aperture one-eighth of an inch in diameter. Three questions were discussed:

1. The age of the ulcer.
2. The time of the perforation.
3. The connection between the ulcer and the inflammation of the serous membranes.

1. It was argued that while the symptoms on admission did not clearly point to ulceration, yet when considered with the subsequent history and the post-mortem appearances, it was clear that the ulcer must have been present at that time. The immediate cause of the hæmatemesis was probably the straining during the severe vomiting which preceded it.

2. That perforation was a cause of the pleurisy and the peritonitis, was rejected on the ground that the hæmatemesis did not begin until after the onset of the three complications; that the vomiting did not cease until four hours before death; and that there was no evidence of extravasation from, or of inflammation in the neighborhood of, the perforation, which was believed to have coincided with the cessation of vomiting.

3. The connection of the ulcer with the pleurisy and peritonitis was rendered probable because of the existence of communicating lymphatics; the occurrence of left pleurisy with an ulcer at the cardiac end; the rarity of the two conditions occurring simultaneously; and the absence of any other discoverable cause.

Dr. Mitchell Bruce said that cases of perforation and peritonitis were of great interest, not only to the physician, but also the surgeon. In Dr. Murray's case it seemed clear that peritonitis preceded perforation.

A Case of Transverse Fracture of the Scapula Below the Spine.

Dr. G. E. Dobson thus writes in the *Lancet:*

Bombardier G. J——, Royal Horse Artillery, was admitted to hospital suffering from pain in the right scapular region, increased by motion of any kind, and especially so by motion of the right arm outwards and forwards. While engaged in assisting to move a heavy iron target he slipped and fell, and was immediately conscious of a sharp pain in the back of the right shoulder-blade, so much increased when he attempted to move the right arm that he was unable to continue to perform his duties. He was quite sure that the target had not fallen on him; while helping to carry it he had slipped on some round stones, and he believed that the weight of the target on his arm when he tried to prevent himself from falling had caused something to give way behind his shoulder.

On examination, there was not the slightest sign of a contusion, or of any external violence. The form of the right shoulder and scapular region did not differ from that of the corresponding parts on the opposite side. The patient was able to place (though with pain) the fingers of the right hand on the left shoulder. On moving the right arm outward from the side, loud crepitus could be heard in the right scapula, and this, with the aid of a stethoscope, could be easily localized to the infra-spinous fossa. The case was diagnosed as a transverse fracture of the body of the scapula below the spine.

The right arm was supported in a sling and fixed by a bandage to the side of the body. A piece of gutta-percha, softened in warm water, was closely applied to, and accurately moulded over, the scapula and shoulder, and maintained in position by a bandage. Fourteen days afterwards the bandages and gutta-percha were removed, when some slight crepitus could still be detected with the aid of a stethoscope. The gutta-percha and bandages were replaced and allowed to remain for ten days, at the expiration of which period the crepitus was found to have altogether ceased; the patient had full use of the limb without pain, and he was discharged to duty.

The injury in question was evidently occasioned by muscular force. The patient slipped when engaged in sustaining a heavy weight, and in trying to make good his foothold and also sustain the weight the latissimus dorsi muscle was brought suddenly into violent action, when the inferior angle of the scapula, across which it extends, was also forcibly moved outwards and backwards against the tense body of the muscle, and, the upper part of the bone being fixed, fracture took place at a point between the opposing forces.

Partially Consolidated Aneurism of the Aorta.

Before the Medical Society of London, October 25, 1886, Dr. Theodore Williams exhibited a case of partially consolidated aneurism of the transverse portion of the arch of the aorta. The patient, a man (who was shown), aged forty-two, a waiter, with a history of rheumatic fever, had complained for one year of pain in the chest, cough, and more recently of short breath and slight dysphagia. He was admitted into the Brompton Hospital in July, 1885, and the diagnosis was aneurism of the transverse portion of the aortic arch pointing in front, pulsation being visible in the upper three intercostal spaces on the left side. Under treatment by rest and iodide of potassium, the patient greatly improved; the dysphagia ceased, and the pulsation became less visible, but irregularity of the size of the pupils was noted before he left the hospital, which he did four months later. He resumed his occupation to a limited extent, but, being attacked with fainting fits, was readmitted in October, 1886, with stridulous breathing, dysphagia, and some dyspnœa, unequal pulses and pupils, the left pupil being widely dilated. Dr. Williams found the aneurism still tolerably solid in front; it had extended backwards, and involved the recurrent laryngeal nerve, giving rise to fixation of the left vocal cord and great stridor of breath. There was also evidence that the trachea was pressed on. The points of interest in the case were—

1. The rapid consolidation of the sac in front, and the cessation of the dysphagia during the patient's residence in hospital.

2. The stability of the clot, even under the unfavorable circumstances of his occupation.

3. The rapid extension of the aneurism posteriorly at a later date.

Dr. Symes Thompson referred to treatment other than iodide of potassium; complete rest in the recumbent posture, and very low diet.

Dr. A. Money asked what the position of the vocal cord was.

Mr. James Black inquired for the presence of cough in this case.

The President referred to the works of

Tufnell, who advocated measures calculated to give the body the most complete rest.

Dr. Williams, in reply, said that the left vocal cord was in the cadaveric position. The patient had a cough of laryngeal quality.

A Case of Hernia into the Umbilical Cord.

Mr. J. Frail Harries reports this case in the *Lancet*, October 23:

In the afternoon of August 25th Mr. Harries was summoned to the Labor ward to see a child just born, who, the nurse said, had a swelling at the umbilicus. The child was a healthy-looking boy who, with the exception of the rare congenital malformation described, was in every respect well developed, and weighed 7¼ pounds. A hernial protrusion into the umbilical cord was found, about the size of a hen's egg. Upon examination Mr. Harries concluded that he had to deal with a partially reducible enterocele, with a sac the neck of which was formed by the skin and the fundus by the coverings of the cord, and with the umbilical vessels spread out over the right side of it. In the absence of the visiting physician, Dr. Hope, he decided upon the following operation. Mindful of the inevitable results of separation of the cord and the exposure of the enclosed intestines, the child having been anæsthetized with chloroform, the sac was opened. The contents of the sac were both large and small intestine, of which five inches of the latter were adherent to the interior of the sac. The bowel beyond, being slightly congested, was quite healthy, and was dissected off without any great difficulty. What he believes to have been the vermiform appendix was so intimately fused with the tissues of the cord as to render dissecting it off impossible; it was therefore ligatured with fine carbolized catgut, and divided close to the sac. After slightly enlarging the hernial opening, the whole contents of the sac were returned into the abdominal cavity. The opening was then closed with a double ligature of thick catgut, in exactly the same way as a nævus is strangulated by Liston's method. The cord with the sac was then cut off about half an inch from the umbilicus. The operation was performed with every antiseptic precaution, and the wound dressed with corrosive sublimate gauze.

During the next fourteen days the wound was dressed twice, and each looked quite healthy; at the end of that time the small remaining portion of the cord separated, and the ligature was removed, the opening being firmly closed. After the operation the bowels acted naturally, and the child took its nourishment freely, some slight sickness being the only trouble. During a rapid convalescence no symptoms of importance were manifested.

Reviews and Book Notices.

BOOK NOTICES.

Transactions of the Medical Association for the State of Missouri for 1886. Pp. 118.

Transactions of the Medico-Chirurgical Faculty of Maryland for 1886. Pp. 254.

Transactions of the Medical Association of Georgia for 1886. Pp. 376.

Transactions of the State Medical Society of Wisconsin for 1886. Pp. 254.

Annual Report of the State Board of Health of New York for 1886. Pp. 579.

This seemly pile of annual reports from active medical bodies in different parts of our Union speaks in self-evident terms of the activity of the American profession. Our space does not allow us to do these volumes justice. Every one of them bears abundant proof of careful observation, carefully put forward; of intelligent and extensive reading; and of a true desire on the side of writers to impart the knowledge obtained by laborious work to others in the same field, and thus to make it the common heritage of the profession.

When such an enlightened spirit pervades the practitioners of any art it cannot but make rapid progress; and these volumes are therefore doubly cheering to the student of medicine, first, by reason of their contents, and next, and not less important, as witnessing to the liberal spirit which pervades all departments of the American profession.

A Manual of the Diseases of the Skin. Fourth edition. J. & A. Churchill, London. Pp. 194.

This small work is a convenient sort of pocket edition of the larger volume of the same author, and is calculated to be serviceable as a reminder for those who wish to refresh their memory on the leading points of this specialty.

—A correspondent writes us that he was attending an Irishman recently, and asked his wife if her husband had any movement of the bowels. "Oh, yes," she said, "he had a 'change of inside' yesterday."

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

SCLEROSIS OF THE COLUMNS OF GOLL.

The columns of Goll (median posterior columns) constitute two triangular columns lying next to the posterior median fissure of the spinal cord. These tracts were described by Cruveilhier, and later still by Goll, as a continuation of the posterior pyramids of the medulla oblongata. They are in fact composed of bundles of nerve fibres quite distinct from the posterior columns so-called, both by their course and mode of development. While the columns of Burdach (the posterior columns properly so called) establish commissural connections between regions of the cord that are contiguous, these posterior median tracts connect portions of the cord that are remote (bulbar and medullary centres); and secondary degeneration of these tracts, when occurring simultaneously with that of other portions of the posterior columns, is propagated much farther upward, and may involve the entire continuity of these tracts.

With regard to their mode of development, the posterior median columns have been shown to have a somewhat later development than the columns of Burdach.

There have thus far been but few observations of systematic leucomyelitis of the median posterior columns. In the description which follows we shall take our data from Vulpian's admirable work recently published.*

One of the first observations was reported by Pierret, in 1873. It concerned a woman sixty years of age at the time of her death. This patient had experienced the first symptoms of an affection of the spinal cord fifteen years before. These consisted in numbness and formications in the hands and feet, principally in the superior extremities, and these phenomena were accompanied by deep, severe pains and sensations of heat. The patient also suffered from pains in the loins and constriction of the thorax. There were added still later anæsthesia of the soles of the feet, and walking became difficult; the patient had attacks of vertigo. Amelioration followed applications of the actual cautery to the lumbo-dorsal region, but the numbness of the extremities persisted.

The symptoms becoming worse the patient was admitted to the Salpetrière. At this period the patient could walk only with the help of a crutch, and she hopped rather than walked; the feet detached themselves with difficulty from the ground, and there seemed to be sometimes propulsion, sometimes retropulsion, sometimes *left latero-pulsion* in her

*Maladies du Syst. Nerveux, t. ii., 1886.

movements. With the eyes shut she could stand erect, but when she attempted to walk she would stagger and fall. Any attempt at walking was followed by speedy fatigue and intolerable pain in the legs.

In January, 1866, girdling pains were for the first time noticed in the lower part of the trunk, and a little later pains of a similar character in the anterior part of the thighs. Cutaneous sensibility was weakened throughout the whole extent of the inferior members, but the reflexes seemed normal.

Death took place in 1870 by pneumonia. The autopsy disclosed as the only lesion in the nervous centres, sclerosis of the median parts of the posterior columns of the spinal cord. With regard to the symptoms of this case, Vulpian remarks that only the tendency to propulsion or retropulsion can be considered as foreign to the symptomatic aggregate by which ordinarily progressive locomotor ataxia is known. As this tendency is exceptionally observed in cases of tabes dorsalis, Vulpian is inclined to refer it to some encephalic complication, of which it might have been the expression. Certainly none of the symptoms above described can be ascribed absolutely to any loss of function entailed by destruction of the columns of Goll. It is a fact that lesion of the median posterior columns so commonly observed in the upper parts of the cord when the tabetic sclerosis occupies the dorso-lumbar and inferior dorsal region ot the posterior columns does not reveal itself by any particular characteristic troubles in the superior members. Vulpian has observed instances of sclerosis of Goll's columns in the cervical region in cases of diffuse peri-encephalitis, without any motor or sensory disturbances of medullary origin.

In a case reported in 1874 by Du Castel of primitive sclerosis of the columns of Goll, in which these columns were affected throughout their whole extent, the symptoms observed during life were incomplete paraplegia, with trembling of the head and of the superior members, but without lightning pains and anæsthesia.

In another case reported more recently (*Progrès Medical*, 1884,) by Camuset, the leading symptoms were paresis of the lower limbs, some enfeeblement of the mental faculties, delirium of grandeur, and an attack of acute mania just before death; there were no symptoms of ataxia. The autopsy disclosed, besides a marked sclerosis of the columns of Goll confined to these tracts in the cervical region, and invading a small portion of the posterior columns lower down, the lesions of chronic cerebral meningitis. The symptoms noticed in this case seemed referable chiefly to these latter lesions. Vulpian concludes an interesting chapter by the remark that thus far clinical observations leave the functions of the columns of Goll enveloped in profound obscurity. Certainly lesions of these tracts do not manifest themselves by any particular morbid phenomena.

"I have," he says, "undertaken on several occasions to study this question by means of physiological experimentation. I have endeavored to cut transversely, or to destroy at a certain point by attrition, the posterior median columns in chloralized dogs. But always when the experimental lesions have affected only the part of the posterior columns bounding on each side the posterior median fissure, I have not been able, in dogs subjected to these vivisections, to note any special symptom apart from the ordinary effects of prickings, or incisions, or lacerations of the posterior columns. Moreover, it is very difficult to destroy entirely and singly this internal part of the posterior columns, so that I have never succeeded in obtaining any significant results. Despite all that may be conceded to observations already published, I believe that if we are ever to know the symptoms peculiar to alterations of the median posterior columns, we must look to clinical medicine for such light, and not to experimental physiology."

SOMETHING MORE ABOUT COCAINE.

Dr. Witzel is one of the most experienced dentists in Germany. That the reader may know how much credit to give to any statement of W., we will mention that he is not only an M. D., but an author, who in Germany is looked upon as the representative of scientific dentistry.

W. recommends the subgingival injection of muriate of cocaine for the painless extraction of teeth. About nine minutes after the injection into the gums of seven drops of a 20 per cent. solution—we see that the dentists in Europe are no longer satisfied with a 2 or 4 per cent. solution—an increase in the action of the heart is suddenly noticed. Then is the time to extract the tooth. The patient is said to feel the application of the forceps, and also the pulling of the tooth, but to show by no exclamation of any kind that the operation is at all painful to him.

W. made some interesting observations which fully coincided with Claude Bernard's researches. The latter, as well known, demonstrated by his experiments that cocaine in

its action on the cerebral circulation was exactly the antagonist of nitrite of amyl. Under the effect of amyl, the cerebral arteries contract, anæmia of the brain develops, the arterial pressure is increased, and the face looks pale. Cocaine causes a dilatation of the vessels of the heart, hyperæmia with diminished arterial pressure sets in in the encephalon, and the face appears flushed and in a general state of venous congestion.

To at once end the anæsthetic condition produced by cocaine, the inhalation of a few drops of nitrite of amyl is the best remedy. In this connection it may be well to remind dentists who may be desirous of employing subgingival injections of twenty per cent. solutions of cocaine that the remedy, at least in this strength, is not without its danger. Dr. Knabe, of Berlin, records the case of a girl, aged eleven, who, after a severe attack of scarlatina, suffered from fatty degeneration of the heart. In her case, the hypodermic injection of cocaine was recommended as a tonic to remedy the frequent fainting fits to which she was subject. Certainly the physician advising such a procedure could have had no idea of the morbid condition underlying these attacks of syncope, nor must he have possessed any knowledge of the physiological action of cocaine. Four or twelve drops—they were never able to discover the exact dose—of a four per cent. solution of cocaine were injected under the skin over the deltoid muscle of the left arm. Scarcely forty seconds later the girl took a deep breath, became deadly pale in the face, and dropped down unconscious. She never recovered consciousness, death ensuing a minute later. In this case nitrite of amyl would have been the remedy indicated.

As not all dentists are graduated physicians, they had better be careful in the administration of such strong solutions of muriate of cocaine. Nitrous oxide gas answers all their purposes, and brings less danger than any other anæsthetic.

Notes and Comments.

A Pathognomonic Sign of Cancer of the Stomach.

A patient was shown at a recent meeting of the Société Médicale des Hôpitaux who exemplifies the condition said by German writers to be characteristic of cancer of the stomach, a condition found by M. Debove to be constant in such cases, and which he proposes as a pathognomonic sign of the disease. In malignant disease of the stomach it will be found that hydrochloric acid is always wanting, whereas it lasts constantly during digestion in every other case. In M. Debove's patient this absence of hydrochloric acid enabled a diagnosis to be made at a period when there was no other symptom of cancer, and the disease was looked upon as dyspepsia, an opinion shared by M. Debove himself until he had ascertained the composition of the gastric juice. Since the beginning of the year the man has been under observation, and the real nature of his disease, now constituted by a characteristic tumor the size of an egg, is no longer doubtful. In reply to questions M. Debove said that he obtained the liquid for examination by means of the œsophageal tube, and that the tests used for distinguishing the acids were those recommended by the Germans. A solution of gentian violet (1 to 5000) gives a blue coloration with HCl. "L'orange Poirier" in saturated solution gives a red reaction with the same acid. Lactic acid is recognized by the increased yellowing of perchloride of iron, and by change in color of a mixture of perchloride of iron and carbolic acid, from amethyst blue to yellow.

Pelletierine in Infantile Disorders.

M. F. Méplain, bearing in mind the difficulty of giving children vermifuge medicine in sufficient doses, and the fact that Dr. Bétancés had administered six centigrammes of pelletierine, which had expelled a tænia, resolved to try this remedy on an infant thirty-two months old, which was suffering from convulsions. M. Béranger Féraud and other writers recommend that pelletierine should not be given to children, on account of the symptoms of congestion of the brain which it occasionally causes in adults. Be that as it may, M. F. Méplain administered to his little patient a large teaspoonful of solution of Tanret's pelletierine, which represents about six centigrammes of the alkaloid; twenty minutes later, twenty grammes of manna, dissolved in a cup of milk, were given. The expulsion was tardy, owing to the insufficiency of the purgatives used, but was, nevertheless, complete. M. F. Méplain, who remained several hours with the patient, observed no alarming symptom. From the observations of MM. Bétancés and F. Méplain, it appears, therefore, that whilst a small dose of pelletierine is sufficient to expel the tænia, the use of the drug is, in the case of children, unattended with the risks which might have been expected from its

physiological action and from the effects observed in adults.

A New "Cure for Cancer."

Dr. Velloso lays claim to having cured several cases of epithelioma of the face and lips with the juice of alvelos (says the *Brit. Med. Jour.*), a plant which belongs to the family of Euphorbiaceæ. It acted as an irritant, and destroyed the diseased tissue, which was quickly replaced by healthy granulations. Of the three different kinds of alvelos (male, female, and wild), the second is considered the most efficacious. It is found at Pernambuco, and although the natives have employed the juice for some time, it has not come into extensive use on account of the severe pain which it causes. The best results were obtained with the juice in a concentrated solid form, and with the addition of vaseline or lanoline. This preparation should be applied with a brush to the affected part (previously washed with a solution of carbolic acid), which should then be left exposed to the air for at least an hour. It should afterwards be covered with lint. This treatment should, as a rule, be repeated every two or three days, and never more than once in twenty-four hours, as the pain of the application is severe, The treatment was more speedily successful when begun before ulceration had occurred.

Pereirine as a Tonic.

The bark of the pao-pereiro tree is said to be a tonic and febrifuge. It contains an alkaloid which was first isolated by Ezequiel in 1838. The name of pereirine has been given to it. The product of that name used in Brazil is an amorphous yellow powder, which is not a pure alkaloid, but contains a compound of amyl, a bitter coloring substance insoluble in water, analogous to glucose, a hydrocarburet, and another crystallized substance, probably a glycosid. Pereirine is very slightly soluble in water, to which it communicates a bitter flavor, but dissolves easily in ether. M. Guimaraes has proved that pereirine produces the following effects:

1. A period of agitation characterized by slight convulsive trembling of the skin, irregular respiratory movements, decrease of the central and peripheral temperature and of the pulse-beat.

2. A period of functional paralysis, consisting in aphonia, diminution in the number of respirations, elevation of temperature, paralysis of voluntary movements.

3. A period of complete paralysis ending in death.

Pereirine, as sold commonly, is impure. M. Fereira has administered doses of two grammes a day in cases of persistent paludal infection.

Aseptol; a New Disinfectant.

This substance is orthophenol-sulphuric acid, and has been known since the year 1841. It has been lately brought forward in France as a disinfectant, and Dr. Hüppe (*Centralb. f. d. Med. Wiss.*, No. 50, 1886,) has made experiments with it which have led him to the opinion that it possesses advantages entitling it to rank beside carbolic acid and bichloride of mercury. Commercial aseptol is a syrupy liquid, having a faint odor of carbolic acid. It is soluble in all proportions in water, alcohol, and glycerine, and even in a 10 per cent. solution has no caustic action upon the skin. Such a solution kills spores of anthrax in thirty minutes, whilst a 5 per cent. carbolic acid solution requires at least twenty-four hours to produce the same effect. A 3 or 5 per cent. solution of aseptol is a true disinfectant for spore-free micro-organisms, or for such as do not form endogenous spores. A 3 per cent. solution was found quite sufficient to disinfect the (previously cleansed) hands. Solutions of aseptol in alcohol, glycerine, or oil (in the last-named no permanent solution takes place) showed no disinfectant power. By heat it is changed into the corresponding para-combination.

External Application of the Juice of Euphorbia.

Since hypodermic injections of papain have been used in diphtheria and cancer, without accident of any kind resulting, the juice of euphorbia has been tried. The results were not very satisfactory. M. Baudry published in the *Bulletin Médical du Nord* the case of a patient suffering from cancroid of the right lower lid, who had himself applied a kind of poultice made of crushed twigs and leaves of the euphorbia (E. helioscopia), a plant containing a milky corrosive juice, employed by country people as a preventive of warts. Two hours afterwards the pain became so intense as to oblige the patient to remove the poultice; he was also attacked by acute conjunctivitis. When first seen eight days afterwards, a whitish ulceration occupied the lower third of the cornea, which threatened to spread rapidly; this was followed by iritis, and hypopyon ensued. Sæmisch's operation

was done the next day, and the patient recovered, with a large adhering leucoma, for which iridectomy will be performed later on. M. Baudry mentions the communication made by M. Landowski, at Grenoble, in 1885, on the destructive action of the juice of euphorbia.

Mirrors for Ophthalmic and other Operations.

During the winter months, the usual daylight is frequently not sufficient for ophthalmic and other operations, nor are operations confined to the few hours during which daylight is present. When operations are performed under such disadvantages, the use of a large concave mirror, of eight or more inches focus, placed upon the brow, will be found of great service, says Dr. W. L. Purves in the *Brit. Med. Jour.* By its means the operator may use artificial light of weak intensity to greater advantage, and regulate its degree and position in a manner he cannot otherwise do.

By using a mirror with two apertures, the ametrope may arrange the lenses he requires behind the mirror; so that he avoids creating the silly impression which sometimes possesses the patient, that any one requiring lenses to operate by is not so reliable as one who can act without them. Presbyops may find this especially useful. A parallelogram form of mirror is, for this purpose, probably better than the round.

Radical Cure after Strangulated Hernia.

Mr. Barling showed a man aged thirty-five on whom he had operated for congenital inguinal hernia eighteen months ago to the Midland Medical Society, December 8. At the operation blood was found in the sac and walls of the intestine, in which there was also a slight laceration. After the strangulation was relieved a tunica vaginalis was made from the lower part of the sac, and the upper part was ligatured and left in the inguinal canal. Two short wire sutures were then passed through the pillars of the ring and walls of the inguinal canal; these were tightened up and cut short. The wound healed by first intention; the patient got up with a truss on in three weeks, and has since worn a truss, until a month ago, when he was instructed to discard it. At the present time there is no return of the hernia, and the external ring is tightly closed; the wire sutures can be felt *in situ*, the testicle feels normal, and slides easily in its tunica vaginalis.

Cholera During Pregnancy.

At a recent meeting of the Académie de Medécine, M. Queirel, of Marseilles, read a paper entitled "Cholera During Pregnancy," in which he stated that, whilst pregnancy is not a predisposing cause of cholera, it appears to make the prognosis less favorable. It has not yet been ascertained whether the disease is transmitted by the mother to the fœtus, but it proves fatal to children at the breast. It is also a frequent cause of abortion. Danger to the mother is greater during the second period of pregnancy, though, should she contract the disease near the end of her time, the child may be born alive, only to die, as often happens, from cholera, a few days after birth. Cholera is more dangerous after delivery, and arrests lactation. From a clinical point of view, the only fact worth recording is, that a severe form of rickets is frequently met with in cases where the mother has had cholera during pregnancy.

Bright's Disease without Albuminuria.

At a recent meeting of the Société Médicale des Hôpitaux, M. Dieulafoy, who has already drawn attention to a form of Bright's disease in which there is no albuminuria, communicated the details of a case which had been verified by post-mortem examination. The patient was a man of 63, suffering from headache and dyspnœa. Neither alcoholism nor syphilis was detected. Dyspnœa dated from several months back, and was characterized by attacks of oppression of a character differing from those which occur in asthma and emphysema. There was slight transient œdema below the malleoli; no albumen in the urine. Soon after admission the patient was attacked with violent delirium and fever. Albumen was then discovered in the urine, and death took place on the eleventh day. The two kidneys presented characteristic lesions.

Case of Snake Bite.

At a recent meeting of the Paris Surgical Society, M. Terrier communicated the case of a showman at a menagerie who was bitten by a snake. Immediately after the bite, the patient tied a ligature tightly round his arm. The wound was afterwards cauterized, but considerable œdema followed. M. Pluzette (Marseilles) injected tincture of iodine locally, and gave an emetico-cathartic, followed by the administration of stimulants, etc. Antiseptic baths were also ordered. The œdema increased, and serious systemic dis-

turbance ensued twelve hours after the accident. The general symptoms improved; but the œdema continued, and gangrene appeared imminent. Eventually, however, the patient recovered, only slight œdema of the arm remaining.

Hereditary Syphilis of the Tongue.

Before the Medical Society of London, Dr. Orwin showed a lad with a curious disease of the tongue. No very clear history of syphilis could be made out, except that he had "snuffles" when a baby. When admitted, the tongue was three times the natural size, and very painful. Under iodide of potassium and nitrate of silver, applied locally, a very good recovery had taken place.

Dr. Angel Money said he had seen several similar cases at the Children's Hospital.

Mr. W. Pye suggested that, in the absence of a history of syphilis in the parents, it might possibly have been primary.

Acetanilide, or Antifebrine.

M. R. Lépine has published in the *Lyon Médicale* an account of a number of observations he has made both on animals and on patients of the action of this drug. He finds that it is a very valuable "nervine" in doses of seven and a half grains, producing as great an effect on the lightning pains of patients suffering from locomotor ataxy as a drachm or so of antipyrin. Like the latter, it lowers the temperature in fevers, and is preferred to antipyrine by patients because it does not produce a condition of semi-intoxication, as antipyrine in large doses is apt to do.

Bicarbonate of Soda in Tonsillitis.

The treatment of tonsillitis by frequent local applications of carbonate of soda, which has been practiced and recommended by Dr. D. Juan Giné, has been put to a series of tests by another Spanish physician, Dr. D. Rovira y Oliver, who deduces from them the opinion that, though it is often beneficial in cases where the parenchyma of the tonsil is affected, it is of much less value than many other applications in cases which are merely superficial and catarrhal.

Trichinosis of Sheep.

At a recent meeting of the Academy of Medicine, M. Johannès Chatin read a paper on trichinosis in sheep (measly mutton). M. Chatin concludes, from his investigations on this subject, that this parasitical affection is not so important as has been supposed. The cysticerci rarely breed in sufficient numbers to cause true trichinosis; and, even should this be the case, there is no danger of their being transmitted to human beings.

Treatment of Erysipelas.

For the treatment of erysipelas Dr. Archangelski has tried a number of applications, and finds that their comparative efficiency is represented by arranging them in the following order: (1) benzoic acid; (2) tincture of iodine and turpentine, as ointment; (3) sulphate of copper; (4) sulphate of iron; (5) oxide of zinc; (6) naphthalin; (7) solution of perchloride of mercury, 1 to 300; (8) chloride of zinc; (9) iodoform.

Quillaja Saponaria as an Expectorant.

Dr. Maslovski has used the root of quillaja saponaria, which was recommended by Kobert, as a substitute for senega in a number of different pulmonary affections, and finds that it is a valuable expectorant. It is, however, contra-indicated where hæmoptysis is present.

Benzoin Resin in Ulcers.

Dr. Woskresenski, writing in the *Russkaya Meditsina* on the use of benzoin resin as a popular remedy for ulcers, says that he has frequently employed an ointment of the strength of four drachms to the ounce spread on lint, and renewed twice a day, with excellent results.

CORRESPONDENCE.

Midwifery in the Country.

EDS. MED. AND SURG. REPORTER:

An article on this subject in a recent number of the REPORTER by me seems to have attracted *some* attention at least, since I have received letters from different practitioners, and seen notices in at least one journal besides yours. Dr. Manchester refers to it in a recent communication, and for fear my position may not be altogether understood, with your permission I will add a few thoughts.

Dr. M.'s obstetrical practice must have been exceptionally good if he had four or five hundred cases in seven years. Not many practitioners meet with so many cases

in so short a time. Some great man has said, "Nothing succeeds like success," which is as true in the practice of medicine in its various branches as in politics or business; and since my success according to the methods I have adopted in my obstetrical practice has been universal, so far as the mother was concerned, except in the single instance mentioned in my communication, I see no reason why I at least should not consider it the best.

As I said, I do not condemn the use of forceps, for the occasion will sometimes arise when they are the *sine qua non*, but I *do* contend they are used many, many times to the detriment of both mother and child, and the everlasting chagrin and disgrace of the medical attendant. I know quite a number of young physicians who were enthusiasts on the subject of the use of the forceps, and others who were, in a measure, forced into their use by the clamor of the public, who to-day would give anything in reason if they could undo the bloody work accomplished by their hands. It looks and sounds a great deal better on paper for some one to give elaborate directions how to operate on a torn perineum, than does the reality of the great, gaping wound staring you in the face, as it were, a monument of your want of skill or judgment.

How much better would it be for a woman to have to undergo twelve or even twenty-four hours' suffering, than to be almost literally butchered, as they sometimes are. Besides this, my experience teaches me that in one of these protracted cases of labor the use of the forceps would be utterly impossible until the os is sufficiently dilated for their introduction, and when dilation does come on, if the physician would "possess his soul in patience" awhile longer, in forty-nine out of fifty cases there would be no necessity for their introduction at all. A great many times I have been called into the country some miles to an obstetrical case where I would be detained as long as twenty-four hours, not because labor had commenced, not because my presence was of any especial use to the patient, but because her mother, or some one who was in charge, supposed the doctor should be sent for; and I would almost necessarily be compelled to stay and wait, Micawber-like, for "something to turn up," fearing if I would go away another doctor would be sent for. What good would all the forceps in the world do in these cases? Some women imagine themselves in labor almost from the time they know they are pregnant. I remember one case where I was sent for every night for nearly a week, and when labor finally began I did not get there in time; and in another case the mother of half a dozen children sent for me one month before labor actually came on. So then I contend because a labor is protracted or even painful, we are not justified in resorting to the use of the forceps, only in exceptional cases.

I do not know that any statistics of the matter were ever kept in any of our hospitals, but I will venture the opinion that the vast majority of operations our specialists are called on to do, for lacerated cervix, torn perineum, etc., are caused by the injudicious use of the forceps, and no man, I care not who he is, is justified in entailing a lifetime of misery on a woman merely for the sake, as is many a time the case, of being considered skillful in the use of the forceps, and that he may count one more in his list of operations. How many conscientious men, "in chewing the cud of bitter reflection," after discovering the irreparable injury done a confiding woman, have rued the day when their hasty zeal led them astray. I have attended a good many women upon whom the forceps had been used, and have attended some upon whom the forceps were used by other physicians subsequent to my attendance, and no trouble arose whatever, except the unpleasantness naturally following an old rent in the cervix. In the earlier years of my practice I have very frequently used a solution of tartarized antimony in rigidity of the os.

In convulsions I would much rather reverse Dr. Manchester's practice, that is, give the hydrate of chloral, combined with potass. bromid. and the morphia in undilatable os.

I cannot believe that any beneficial result could be derived from scratching the cord-like os, as recommended by Dr. M.

Chloroform certainly gives relief when there are no indications against its use, but it just as certainly retards labor, in most instances, because of its well-known property of relaxing the muscular system, as can be seen when it is administered for the purpose of reducing a hernia or dislocation.

I intended to mention in the beginning of this article, and forgot it, that I had a letter from Dr. Batchelder, of Pelham, N. H., commendatory of my former communication, and which contains so many good things, that I am almost tempted to send it to you for publication, only that it is a private letter. Dr. B. has been in practice fifty-two years, long before I was born, and with all the vast experience crowded into more than

half a century, he has only used the forceps "perhaps a dozen times," and for that, or some other reason, he has only lost one woman in confinement, away back in 1838.

Wm. F. Mitchell, M. D.

Addison, Pa., Jan. 10, 1887.

Intra-Ocular Cancer.

Eds. Med. and Surg. Reporter:

Upon reading the article in a recent issue of your journal on "Intra-Ocular Cancer" of a child, I am forcibly reminded of a similar case occurring in my practice a few years ago. I will briefly state the circumstance and treatment, with the results.

Patient, child, female, aged four years, was brought to my office, in good state of general health, with a defect noticeable in the left eye—parents said of recent origin. Upon a close examination I was able to discover a small spot, seemingly of a whitish character, with great defect in vision. Suspecting serious trouble, I at once directed them to an oculist, advising its removal. With that I lost sight of the case. But to my great surprise, about two months later, the child was again brought to my office with eye fairly bulging out of the orbit. Upon inquiry as to why an operation had not been porformed. they gave some flimsy excuse, and ended with the request that I do what was necessary in the case. I at once advised the complete enucleation of eye, and removal of the entire contents of the orbital cavity, which was immediately agreed to, and selecting a day suitable, I carefully removed the eye, and scraped the orbital cavity as clean as I could, in fact applying caustic as completely as possible. The little one bore the operation nobly, and, barring the unfavorable prognosis, all seemingly looked well. But, as was not unexpected, in just one month from the date of the first operation, there was such a renewal of the growth as to require a second operation, which was accordingly done, removing this time a growth as large as an ordinary hen's egg. The same scraping and cauterizing as before was indulged in, and the same prompt recovery. Again the little child made an attempt to live, but again the horrible disease manifested itself in the shape of a growth as large or larger than the former one, this time with a general dropping of the vital forces; but as the strength was sufficient, and as previous operations were well borne, I again operated, and again extended to the little sufferer a short lease of life. But when the next time, in the short space of six weeks, a cancerous mass hung out upon the cheek the size of a large goose egg, the little one succumbed to the constitutional contamination, and with no further attempt at surgical relief, quietly sunk away and was released from her suffering. Such a continual recurrence, such tolerance of surgical treatment, is seldom witnessed; and it was, as may be imagined, almost a relief to me to see the poor little child at last free from pain and the surgeon's knife.

C. G. Hollister, M. D.

Union City, Pa.

Causes of the Uncertainty of Bovine Virus.

Eds. Med. and Surg. Reporter:

I noticed in the Medical and Surgical Reporter of last week that you explain the frequent non-success of vaccination with bovine virus by the fact that the virus becomes too stale before it is used. For the last ten years, with the exception of a very few cases, I have used exclusively cow-lymph for vaccination, procured from different vaccine farms. Within the last year or two, however, I notice that it becomes more and more difficult to successfully vaccinate primary cases with this virus. In primary cases, I no longer expect more than one out of four or five children to take the vaccination, even when the virus is apparently perfectly fresh. The cause, it seems to me, must lie in the mode of charging the points or quills—either in too great attenuation of the original lymph, from the desire to prepare too great a number of points from one successful cow-scab, or in some defect in preserving the points at the vaccine farms. It is true, bovine virus, owing to the difference between the epidermis of man and oxen, does not take as readily as humanized virus, but the most frequent cause of failure, from my experience, is the worthlessness of the points. Yours truly,

W. F. Muhlenberg, M. D.

Reading, Pa.

News and Miscellany.

The Surgeon and the Jockey.

The *Pall Mall Gazette* says that Archer, having been bitten or otherwise injured by a horse on one occasion, called on Sir James Paget. The eminent surgeon having bound up his wound, Archer requested to know how long it would take to heal. "Oh," said Sir James, "I think in three or four weeks you will be all right."

"But shall I be fit for the Derby?" asked Archer.

"Ye-es," was the reply. "Oh, yes! I think you may go to the Derby."

"No, but you don't quite understand me, Sir James," persisted the jockey. "I mean, shall I be fit to ride?"

"Well, I don't know," was the answer. "Better drive; better drive!"

Archer, rather taken aback by this very innocent and unexpected rejoinder, had to explain. "I am afraid, Sir James, you scarcely realize who I am?"

"No," said the surgeon, politely, referring to the patient's visiting card. "I see I have the honor of receiving Mr. Archer, but—"

"Well," said Archer, "I suppose I may say that what you are in your profession, Sir James, that I am in mine," and proceeded to tell him what that profession was.

The famous surgeon, on learning the status of his visitor, was at once greatly interested, and asked him eagerly many questions, among others, what would be his loss supposing he should be unable to fulfil the Derby engagement? to which Archer replied: "About $10,000." His average annual income he stated (if I mistake not) to be about $40,000; upon which Sir James is said to have remarked: "You may well say that what I am in my profession, that you are in yours. I only wish that my profession were as profitable as yours."

A Six-Fingered Family.

An interesting communication, having reference to twenty-seven individuals and five generations, is summarized as follows in the *Rev. Internat. des Sci. Méd.*, November, 1886. First generation: Man, born in the year 1752, had six toes on one foot. Second generation: A son with six toes on one foot; a daughter, normal. Third generation: This daughter had five children, amongst whom were a son and daughter each having six fingers on each hand. Fourth generation: The daughter last mentioned had eight children, including one son having six toes on one foot, another son and two daughters each having six fingers on each hand, and one daughter having both six fingers on each hand, and six toes on each foot. Fifth generation: The daughter last mentioned (the *Revue* makes a mistake here) had three children, including a son, doubly deformed like his mother, and a son with six fingers on each hand, the feet being normal. Moreover, one of the two daughters of the fourth generation (with only the hands affected) had eight children, several of whom were normally developed, but the rest were deformed as follows: One daughter had an osseous thickening at the digital extremity and on the outer border of the fifth metacarpal; one son had six fingers on each hand, and six toes on each foot; and another son had six fingers on each hand. Thus, in the first generation one person was affected, and in the second also one; in the third, there were two cases of deformity; in the fourth, five; and, in the fifth, in all five, that is, fourteen deformed persons altogether during five generations of this interesting family.

Cholera and Quarantine in Buenos Ayres.

According to the latest advices from Buenos Ayres, the existence of cholera in that town was officially admitted early in November last, and in accordance with the traditions of the States in that locality, the outbreak was the signal for the immediate imposition of quarantine of the harshest and most grotesque character. The adjoining provinces refused to admit anything or anybody from Buenos Ayres; whilst the latter retaliated by refusing to allow even correspondence from the other provinces to cross its borders. Monte Video absolutely prohibited any communication, even in writing, with its rival, Buenos Ayres, and we are not sure whether even telegraphic messages did not come within this prohibition. And yet, according to recent newspaper reports, it would seem as if cholera has invaded Monte Video itself. Meanwhile, the foul blots in the sanitary condition of the neighborhood remain unheeded and unremedied, the shipping and commerce are deranged, and the immigrants to the district are huddled together in the lazaretto, or have to remain on board their respective vessels.

Accidental Inoculation of Anthrax.

A case of a healthy farm-laborer contracting anthrax from a bull affected with the disease, has recently occurred in Shropshire, England. It appears that, on November 25, this man was required to slaughter a bull that had taken suddenly ill, and was apparently in a dying condition. During the operation his arm became smeared with the animal's blood. On December 2, a small "boil" appeared on the arm. Other similar lesions subsequently developed, and the man became weak and ill; he was admitted into the Salop Infirmary on December 8. After excision of one sore and cauterization of the

others, the patient recovered, and by December 17 he regained his usual health. How the bull became affected with anthrax does not seem to have been as yet satisfactorily explained, but that it was anthrax from which it suffered has been established by competent examination of the animal's blood.

Local Celebrity of a New York Medical Editor.

As Dr. Geo. F. Shrady, of New York, editor of the New York *Medical Record*, is such a stickler for keeping the names of his fellow editors out of the newspapers, we respectfully ask his explanation of the following felicitous tribute to his skill printed in the *New York Tribune* of recent date:

Dr. Geo. F. Shrady, of New York city, performed a noticeable surgical operation upon a young son of Mr. W. MacRussell, of Saugerties, N. Y., on Saturday last. The child's leg had been broken some time since, and it had become united so improperly that he had lost all use of it. The doctor removed a portion of the defective bone and reset the limb successfully. Various promi nent surgeons witnessed the operation. The patient is doing well.

Will not our brother editor relieve us by stating that it was "without his knowledge" and "contrary to his wishes?"

The London Hospitals in 1886.

Mr. E. W. Taye, the editor of the *Charity Record*, has summarized a few salient facts showing how far-reaching are the benefits conferred by the London hospitals and dispensaries, which depend chiefly upon the voluntary generosity of the public. Last year, about 120 of these charities had a total accommodation of between 6,000 and 7,000 beds—of which the London had 790; the Metropolitan Convalescent, 500; St. George's, 350; Brompton Consumption, 320; St. Mary's and Middlesex, about 250 each; Westminster, University College, King's College, and London Fever, about 200 each; City of London Chest, 164; Royal Free, 160; Charing Cross, 154; and Seamen's Hospital, 126. Relief was given at the 120 institutions to upwards of one million patients—that is, in round figures, about 60,000 in-and 940,000 out-patients.

Medical Literature.

Under this general title Mr. Howard Challen, of 150 Nassau street, New York, is preparing for publication the lists of books issued by medical book publishers in uniform octavo style. It will have an index of all medical, surgical, dental, and sanitary books, arranged alphabetically, under author, subject, and title, and all periodicals, with subscription price relating thereto, making it indispensable to book-buyers, for whom it is especially intended.

Authors and book-buyers will obtain further information by addressing the publisher.

Ants' Jaws to Hold Wounds Together.

The *San Francisco Argonaut* says that a citizen of Valrosia, Florida, wants to send some of the big red ants of that region, called "bull-dog" ants, to surgeons for use in fastening wounds of the intestines. He says that if the edges of two pieces of soft paper are held together and a bull-dog ant held so that he will clutch both sides, and his head be then quickly twisted off, the ant becomes a fixture in that position. He says that Spanish surgeons use the bull-dog ants as sutures in that way.

Therapeutic Jottings.

Dr. George H. Horn, of this city, has found that lanoline, in combination with iodoform, reduces very materially the generally so offensive odor of the latter.

He has also observed that the addition of a small quantity of common salt to a solution of the bichloride of mercury holds the latter effectually in suspension, an end much to be desired in dealing with a drug of such potency.

The Cholera in Europe.

No fresh cases of cholera have been reported, says a telegram from Rustchuk, of December 22, since the first eight deaths, which occurred about nine days ago. The sanitary cordon established around the infected village is still maintained. The Roumanian Government, having taken precautionary measures against arrivals from Bulgaria, the Bulgarian authorities, not admitting the prevalence of cholera in the country, have adopted similar measures as regards arrivals from Roumania.

Beri-Beri in the Dutch Indies.

It is officially stated that during the year 1885 there were 5,388 persons in the Atchin colony treated for beri-beri, of whom 235 died and 842 were incapacitated for duty. Up to the present time no regulations seem to have had any effect on the ravages of this strange malady.

The Vaccination of the Austro-Hungarian Army.

Struck by the wonderful fact that in the German army the compulsory vaccination had reduced the mortality from small-pox to *nil*, the Crown Prince Rudolph of Austria had been led to urge a similar precaution for the Austro-Hungarian army, and within the last few months, the *Evening Standard* observes, every soldier has been compulsorily vaccinated. The result is that whereas in Pesth a small-pox epidemic of great severity has been raging among the civil population (who are under no compulsion), there has not been a single case among the numerous troops of the garrison at Pesth. Of course all this will be explained away by our anti-vaccination friends, and the many who died of small-pox will be regarded as better off than those who have been saved by vaccination. But the majority of people will not go wrong over such plain facts.

Oleomargarine.

The French Chamber of Deputies has adopted a measure prohibiting offering for sale, importing, or exporting oleomargarine or any substance bearing the name of margarine, intended as a substitute for butter. The adulteration of butter with margarine, grease, oil, or any other substance whatever, is also forbidden.

Items.

—Dr. Alfred Meadows, of London, has been elected an honorary member of the Washington Obstetrical and Gynecological Society.

—Prof. Pajot, of the Paris Faculté de Médecine, recently attained his seventieth birthday, the time at which all professors in French institutions must retire.

—One of our readers was called to see a baby, and found the mother holding it. "Is your baby troublesome?" he asked. "Yes, very," she said; "I have had to 'sit under' him all day."

—A piece of sacred music has recently been composed and performed in private by one of the professors of the medical faculty of Madrid, which is highly spoken of by the press of that capital.

—Charles James Fox, M. D., of Willimantic, Conn., has been appointed Surgeon-General of the State of Connecticut, and entered upon his duties as a member of Governor Loundsbury's staff on the 7th inst.

—Dr. Albert Burckhardt-Merian, Professor of Otology in the University of Basle, and one of the editors of the *Correspondenz-Blatt für Schweitzer Aerzte*, died recently, after a prolonged and extremely painful illness.

—An action has been brought by order of the German Chancellor against Dr. Oidtmann, editor of the *Impfzwanggegner* (Anti-compulsory vaccinationist), for libeling Prof. Koch and Privy Councilor Köhler.

—The Sacramento *Medical Times* is the title of a new monthly journal, the first number of which will appear in March, under the editorship of James H. Parkinson, L. R. C. S., and Wallace A. Briggs, M. D., of Sacramento, Cal.

—We are requested by Dr. Casper to state that the original communication which appeared under his name in the REPORTER for November 21, 1885, was by Dr. Kadner, and was merely forwarded to us by Dr. Casper. The mistake was our own in crediting it to the latter instead of the former.

—The Committee on Hygiene of the Medical Society of the County of New York have waited upon the Board of Health in a body for the purpose of urging upon them the passage of an ordinance requiring the baling of all stable-manure in the city; the Board has as yet arrived at no decision in the matter.

—The members of the National Wholesale Druggists' Association have been supplied with petitions to Congress for the repeal of the internal revenue on alcohol. This is in accordance with a resolution adopted at the last meeting. There is considerable prospect, says the *National Druggist*, of the object being accomplished.

—About three hundred students of the Jefferson Medical College in this city have united in a petition to the Faculty of that institution, asking that the eminent ophthalmologist, Dr. William Thomson, now professor of that branch in the Jefferson, shall deliver a didactic course of lectures on the eye and its diseases in addition to the clinical instruction already provided.

QUERIES AND REPLIES.

DOES FREEZING RUIN LEAD WATER?

EDS. MED. AND SURG. REPORTER:

In your Query column of the REPORTER, will you please tell me if liq. plumb. subacet. is ruined after freezing? Mine did so recently, and after thawing refuses to make solution again. What is best to do with it? E. I. P.
Campte, La.

Pallas Syringe.

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1054-1556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infections and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

R. A. GIVEN, M. D.,

WORM-LIKE BODIES FROM THE HUMAN THROAT AND MOUTH.

BY CHARLES E. FAIRMAN, A. M., M. D.,

Of Lyndonville, N. Y.

February 6, 1883, Mrs. J. G. consulted me for various aches and pains, which, she thought, resulted from some grave internal troubles, but which seemed to me purely imaginary. Among many symptoms narrated, she said that at different times she had taken "worms" from her mouth and throat, which were hair-like in form, transparent, long, and a source of great annoyance. She was, apparently, anxious to ascertain their nature. I thought at once of MERMIS ACUMINATA, and asked her if she had eaten freely of apples of late and was informed that "she never ate apples." I therefore requested her to save some of the worms, bring them to me, and I would examine them microscopically and report.

February 12, 1883, Mr. G. brought one of the worms, nicely wrapped in thin paper, to my office. Upon examination, I found it to be a *cotton fibre*. The microscope showed adherent starch grains, oil globules, muscular fibres, and general salivary debris.

I immediately told Mr. G. that his wife was mistaken, or feigning her sickness; that the "worm" was a fibre from a cotton handkerchief (or similar fabric) which she had put in her mouth after dinner, accidentally or otherwise, and that she had eaten "meat and potatoes" for dinner.

Some time subsequently the husband admitted the substantial truth of my hypothesis. I expected to hear no more from the case. But I was mistaken. On July 12, 1884, Mr. G. came to my office and said that his wife *had passed*, by the bowels, a *strange* animal, and that it *did* have hairs all over its body. She desired me to bring my microscope to their residence so that she also could see the "animal." I accordingly made the visit, and found that the animal which passed the bowels was the larva of a blow-fly. The maggot was still alive. I took the specimen and, after preparatory treatment, mounted it in Canada balsam, and still retain it. If the reader will refer to the fourth edition of Beale's "Microscope in Medicine," plate XLIII., fig. 1, an exact representation of my specimen will be found. One will see, also, the appendages which Mrs. G. took for the hair-like worms. After this failure to convince me, Mrs. G. gave up the idea of "worms." Old ladies are wont to say, "You doctors, I know, don't believe in worms."

The practical lesson which may be drawn from the above is that the physician should familiarize himself with the microscopic appearance of common food materials, fibres of textile fabrics, common insects, etc. When he has so familiarized himself, he will be armed against deception in many instances.

MERMIS ACUMINATA RUDOLPHI, to which I have referred, is a thread-like worm, a parasite of the larva of Carpocapsa Pomonella (a fruit moth of the apple). In the proceedings of the Academy of Natural Sciences, Philadelphia, for February, 1875, Dr. Leidy remarked that "twenty-five years ago (*Proc.* 1850, p. 117), he had described a worm belonging to the collection of the Academy, and labeled as having been obtained from a child's mouth, which was evidently the same species.

It having been in a child's mouth is probably to be explained by supposing that the child had eaten an affected apple. It was described as filaria hominis oris. Body white, opaque, linear, thread-like, mouth round, simple, posterior, extremity obtuse, furnished with a short curved epidermal hooklet $\frac{1}{300}$ inch in length by $\frac{1}{2000}$ inch in diameter at base. Length five inches, seven lines; greatest breadth $\frac{1}{65}$ inch; breadth at mouth $\frac{1}{250}$ inch; at posterior extremity $\frac{1}{80}$ inch.

Mermis is a genus allied to Gordius, the "hair-snake," which may be often seen in pools of water. It belongs to the NEMATOIDEA or "Thread worms," of which order Ascaris, Oxyuris, and Tricocephalus are well known to physicians. Huxley classes it with the group HOLOMYARIA, which he says includes several aberrant forms. "Thus *Tricocephalus* has no anus; *Mermis* has no anus, and the alimentary canal is rudimentary, though it possesses the lateral areas, and the males have spicula. *Gordius* has no lateral areas."

Mermis has been found quite a number of times in apples, and has always excited no little alarm in those unfamiliar with its history.

According to Ransom, there can be no doubt that ascaris lumbricoides spontaneously wanders toward the external apertures, and may escape from the mouth or nose. According to Huxley, Ascaris nigrovenosa is parasitic in the lungs of frogs and toads; and that CUCULLANUS ELEGANS, in its sexual condition, inhabits certain fresh water fishes, snch as perch, etc.

I have alluded to the two last Nematoidia for the following reason: It will do no harm to the general practitioner to acquaint himself with the entozoa of common animals, as well as human entozoa. They are often consulted with reference to parasites found in various food articles. Thus the farmer asks you for information on anguilla scandens, a nematoid which infects his wheat. In dissecting a cat for histological purposes it may happen, as it has to the author, to meet with ascaris myspox (Zeder), the common round worm of the cat.

In 1885 some fishermen in my locality were peddling fish called "siscoes," taken from Lake Ontario. One day some person found a worm in a siscoe, and straightway terrible tales of trichina-like forms in those siscoes were started. Some of the fish were handed me for examination, but being unable to tell the genus, I sent specimens to Dr. Leidy, of Philadelphia, for name. He wrote me as follows, under date of March 8, 1886:

"The two letters of January 20th and 30th, and the bottle with the specimens of the parasites of the sisconet, were duly received. The worms are a species of 'thorn head,' echinorrhyncus, but I am uncertain whether it is a described form. To determine the question, the worm should be examined living or fresh, so as to ascertain color and other characters."

Those who are interested in following up the subject are referred to the following bibliography on mermis:

MEDICO-LEGAL NOTES.

BY HENRY A. RILEY, ESQ.,

Of New York.

CAPITAL PUNISHMENT IN NEW YORK.

The commission appointed by the Legislature of New York at the session of 1886 to consider the question of capital punishment will soon make its report, and it will be awaited with some interest, especially in view of the effort made by some sentimentalists to induce Governor Hill to commute the death sentence of Mrs. Druse. The murder of Mr. Druse by his wife was one of the most fiendish crimes committed in recent years, the wife literally chopping her husband to pieces and forcing her children to aid her in disposing of the remains. It is thought by some that no woman should ever be hanged for murder, and but two have ever been put to death in this manner in the history of the State of New York, but there is no valid reason why an exception should be made in the case of women so long as the statute makes no difference between the sexes. If an exception were ever to be made, this case seems the most inappropriate to take advantage of, by reason of the very enormity and barbarity of the crime. Governor Hill

has not yielded to the clamor in favor of the commutation of punishment to life imprisonment, but has reprieved Mrs. Druse so that the Legislature will have an opportunity to consider the question and abolish capital punishment in the case of all women if it desires to. There is likely to be quite a discussion of the question when the Legislature meets.

MEDICAL EXPERT TESTIMONY.

An interesting point in medical expert testimony was recently decided in the Supreme Court of Wisconsin, and we will give the opinion of the court in full: "The deficiency in the nervous system of a child, with which a woman who was wrongfully imprisoned was quick at the time she was arrested, is not a proper element of damages in an action by the woman for malicious prosecution; and testimony of a physician who attended the woman while in jail, and assisted at the delivery, but who had not seen the child for more than a year thereafter, is not competent to show that the neurasthenic condition of the child at that time was due to the nervous shock inflicted upon the mother by the arrest and imprisonment. At the time plaintiff was confined in prison she was with child, and was delivered thereof in the following December. Dr. Robinson attended her in prison, and officiated at the birth of her child. He testified that he found her in prison, suffering nervous prostration, followed by indigestion and debility, and the drift of his testimony is that in his opinion such condition was produced by the nervous shock caused by her arrest and incarceration, and still continues to some extent; and that while she may recover, he does not look for a speedy recovery. He also testified that a pregnant woman in that condition would be liable to give birth to a monstrosity or a deficiency; also that the plaintiff's child when born was perfect so far as he then knew; but that at the time of the trial nearly two years later it was defective in the brain, spinal cord, and nervous system. Dr. Robinson went to Europe in April, 1884, and about four months after the birth of the child, and did not return to Wisconsin until May, 1885. It does not appear that he knew or suspected the child was deficient until after his return. He was permitted to testify, against the objection of defendant, as to the nervous prostate condition in which he found the plaintiff in July, 1883. Dr. Robinson was a competent witness to the condition of the plaintiff when he saw her in jail and afterward. He was competent also to give his opinion as an expert as to the nature and probable future effects of her condition upon herself and perhaps upon her unborn child. But in view of the fact that it is a common knowledge that there are numerous causes for physical, mental, or nervous deficiency in children; that healthy women do sometimes give birth to deficient children; that nervous or otherwise unhealthy women often bear healthy children; and that Dr. Robinson detected no defect in the plaintiff's child until it was nearly a year and a half old, we think the authorized limits of expert testimony were greatly exceeded when he was allowed to give his opinion that the deficiency in the plaintiff's child was caused by the nervous prostration of the plaintiff during her pregnancy. The testimony should have been excluded. This testimony may have been and probably was prejudicial to the defendant."

PROHIBITION IN KANSAS.

The Attorney General of Kansas, in his report to the Governor of the State, makes some statements and recommendations which will be of interest to the druggists of that State. Since the prohibitory liquor law went into operation in Kansas, a considerable part of the trade of the saloons has gone to the drug stores, which were excepted by the statute from the ordinary penalties of liquor selling. It has been claimed that many of the drug stores were little else than saloons, and an effort has been made to curtail the rights of sale now held by them. The Attorney General sides with those who would force the apothecaries to keep to their legitimate calling, and suggests an amendment which, "in addition to the affidavit now made by the druggist that the statements filed by him each month represent all the liquor sold by him, requires him to state, under oath, that the persons applying for the same were persons known to him, were identified, and that the liquors sold were desired for legitimate purposes, and that in addition thereto the applicant sign his own name and not a fictitious one to the statement."

THE LIABILITY OF WIDOWS.

The Probate Court of St. Louis has recently been considering the question whether a merchant who sold goods for mourning apparel to a widow to enable her to attend her husband's funeral had a claim against her or the estate of the husband. The administrator of the estate, which was insolvent, claimed that the purchase was a personal matter. The judge took a contrary view, however, and held as follows: "So far as the articles furnished were necessary to enable the widow to appear in decent costume

at the obsequies to pay the last tribute demanded by the solemn occasion of putting to rest the remains of a departed husband, they seem clearly to constitute 'reasonable funeral expenses' which the statute directs to be allowed against the estate whether it be solvent or otherwise. In the case under consideration the evidence shows that the goods were reasonable and suitable to the occasion, and that the widow could not have appeared at the funeral without them, without disregarding public custom and offending public sentiment."

WHO MUST PAY THE NURSE.

The Supreme Court of Iowa has just decided that where an employee of a railroad company was injured by an accident, for which the company was responsible, it will not be liable for services and meals furnished nurses and others in attendance by the physician's orders, unless he was expressly authorized to make a contract for them.

ON PRIMARY LATERAL SCLEROSIS.

BY PROFESSOR A. VULPIAN.

Dean of the Faculty of Medicine, Paris, France.

Does the affection named "spasmodic spinal paralysis," by Erb, "spasmodic tabes dorsalis," by Charcot, really exist with all the attributes of a distinct disease? To be able to respond affirmatively to this question, one would have to show that the aggregate of morbid phenomena grouped under such particular denomination is the symptomatic expression of a constant pathological process, uniform, or nearly so, always undergoing evolution in a definite part of the constituent elements of the spinal cord. In other words, there must in every case be the same medullary lesion, with identical and pretty nearly invariable localization.

Now the cases recorded of this disease are thus far very few, and what shows that the diagnosis is not always easy, is that in one of the observations recently taken from reports of Charcot's cases, and given in Beton's thesis as a typical case of spasmodic dorsal tabes, the microscopic examination revealed the existence of disseminated sclerosis.

In a case recorded by Madder, under the name of spastic spinal paralysis, the post-mortem disclosed softening of the dorsal region of the cord; there was no sclerosis.

Naturally, then, various authorities have expressed doubts as to the legitimacy of the nosological creation of Erb and Charcot. Leyden, among others, has endeavored to show that the symptomatic aggregate of spastic spinal paralysis has nothing which is characteristic, and that all these symptoms may be observed in a certain number of cases of varied affections of the cord, when the lesion is seated in the dorsal region of this nervous centre. Among the affections in the course of which he claims to have noted this train of symptoms, he cites traumatic myelitis, myelitis by compression, spinal paralysis consecutive to acute diseases, syphilitic paralysis, and peri-myelitis.

R. Schulz alleges that one may observe all the symptoms of this affection in cases where the disease is not primary but secondary. He reports two cases in which were observed the characteristic symptoms of spasmodic spinal paralysis; progressive paresis of the extremities, rigid muscular contractions, sensibility intact, a normal state of the genital and urinary functions, augmentation of the tendinous reflexes. In the one case, there was sclerosis of the lateral columns, secondary to a tumor of the medulla oblongata. In the second, the spinal cord was healthy, but there was a colossal internal hydrocephalus. Schulz concludes that the sum of symptoms described as peculiar to lateral sclerosis is produced whenever the pyramidal tracts are affected in a certain region of the cord, or whenever these tracts become the seat of a functional excitation, even without the least material alteration.

Two cases of a similar nature to those given by Schulz are recorded in *Brain*, a journal of neurology, January, 1884; with the symptoms ordinarily ascribed to spasmodic spinal paralysis there was lack of the lesions of lateral sclerosis.

With these exceptions the fact must not be lost sight of that there are cases on record, though few in number, in which, with the clinical syndroma described by Charcot and Erb, the autopsy has disclosed lesions of a primary nature limited to the lateral columns of the cord. The sum of the symptoms observed during life corresponded exactly to the *tabes spasmodique* of the above-mentioned authors. I may, for instance, cite an observation by M. Stoffela.* This case offers a particular interest in that it concerns a patient in whom the affection had commenced at the age of 75 or 76 years, and who had all the symptoms of spasmodic tabes well marked when examined at the age of 78 years. There was notable enfeeblement of the inferior extremities; he walked without raising the feet, which simply shuffled along the ground; the knees were stiff, and the thighs were rigidly drawn together; often

*Thesis of Jubeneau, 1883.

when attempting to walk there were cramps in the muscles of the calves and thighs. The uncertainty of gait was noticed in the patient when his eyes were shut.

During the two years which elapsed between this period and the death of the patient by pneumonia, there were no indications of muscular atrophy; the contracture persisted. There was neither diminution nor perversion of cutaneous sensibility; micturition and defecation were normal. The cutaneous and tendinous reflexes were exaggerated; the spastic symptoms had become more frequent and more intense.

At the autopsy was found a sclerosis of the lateral columns the whole length of the cord, most pronounced in the thoracic and lumbar regions. The whole extent of the lateral tracts was involved in the degeneration, which bordered posteriorly on the posterior cornua.

This case is open to certain critical objections. M. Leyden denies its validity on the ground that there was no microscopical examination; that the disposition of the sclerosis was not quite what one generally observes in cases of primary sclerosis of the lateral columns; that the encephalon was not examined, so that it was impossible to tell whether there might not have been in this patient an encephalic lesion with secondary degenerations.

These objections seem to me be rather exaggerated. None of the symptoms warrant the supposition of a cerebral lesion, and the absence of all muscular atrophy justifies the opinion that the gray substance was healthy.

Another observation published by M. Morgan seems to be exempt from every valid objection, and if this be so, it is a good instance of primary sclerosis of the lateral columns, finding expression in the congeries of symptoms belonging to the clinical pictures of spastic spinal paralysis given by Erb and Charcot.

The patient, A. B., a man aged 45 years, dated the commencement of his disease to exposure to cold and wet during a night two years before, when he was engaged in hunting. A few days after the severe chill which he then received, he experienced a certain enfeeblement of sensibility and movement in the right inferior extremity; then, after several months, the left inferior member was taken in its turn. A little later were manifested all the characteristics of spastic paraplegia.

When he was observed in the month of May, 1880, there was paresis with rigidity of the inferior members; the reflexes were exaggerated; the sensibility was intact and there was no paralysis of the sphincters; no ataxia was noticed; the cerebral functions were intact. The lumbo-vertebral region was painful to pressure, and the patient could not sit up in bed without being helped.

This patient died July 7, 1880. The examination of the cord made by Dr. Dreschfeld revealed the existence of sclerosis of the lateral columns. This sclerosis, which was very easily noticed in the cervical and lumbar regions, was most marked in the dorsal regions. All the other portions of the cord, gray substance, and white substance, were absolutely healthy.

M. Morgan sent sections of the cord to Prof. Charcot, who found the lesion to be a true sclerosis of the lateral columns, and wrote to M. Morgan that "this is the first case on record in which the post-mortem examination has demonstrated the existence of a lesion wholly confined to the lateral columns, without participation of the gray substance or the posterior tracts."

BOULIMIA—CASEOUS PNEUMONIA AND DEATH BY ACUTE TUBERCULOSIS.

BY CHAS. BAUER, M. D.,

Of Philadelphia,

Late Assistant Physician to the O. P. Department of the Hospital of Jefferson Medical College.

The patient, R. K., came to my office, January, 1886, complaining of dyspepsia. She appeared greatly emaciated, except in face, which was pale, ears and conjunctiva expressing marked anæmia. Her manner was quick, nervous, and emotional, almost bordering upon the hysterical. I gleaned the following history: Family history good; she was twenty years old; first menstruated when thirteen, and performed that function regularly until her sixteenth year. At fourteen she took employment in a silk-goods factory, but believing that the work was too much for her, left the place six months later, and subsequently went at shoe-pasting. At this time (at fifteen years of age) she was strong, rosy, and stout. About nine months later, she went back to the factory, where some depraved associate taught her the practice of a vicious habit, which she indulged for over a year.

I mention this, not so much because of a belief that it may have been the cause of developing the symptoms of boulimia, which, considered purely as a nervous derangement of part of the digestive apparatus, would

not seem unreasonable, but because it belongs to the history of this, in many respects, singular case. At all events, it was not long before grave nervous phenomena manifested themselves. Menstruation became irreguar and scanty, she began to lose flesh and color, slept poorly, would cry on the least provocation, and a morbid, insatiable craving for food developed. She wanted to eat everything eatable she saw, nor would any quantity satisfy her desire for more. If a loaf of bread was placed before her, she would not stop eating of it until the whole was consumed, and then wanted more, and "when I am quite full I am still as hungry as when I began." It was the same way with drink: if she drank a glass of ice water, she was tempted to empty the cooler. This was after a time followed by dyspeptic symptoms, of which pain over the epigastrium and constipation (probably due to paresis of the bowel) seemed to have been the most prominent. A physician whom she consulted, said she had some liver trouble and dyspepsia. Her mother and those who observed her voracious appetite now insisted that she must have worms, and took her to a "celebrated" worm-doctor of this city, who, of course, diagnosed "Worms, worms, worms, madam," and plied her with $22 worth (?) of his "infallible" nostrum, with no result except to add to her debility and dyspeptic troubles. In the fall of '83 she contracted a severe cold, which confined her to bed for four days, being delirious part of the time. The physician called pronounced her ailment congestion of right lung. In about a week she was able to go back to her work, has not taken cold since, *nor been subject to cough.*

She came now on account of this inordinate appetite, her wasting, weakness, nervousness, somnolence, dyspepsia, and constipation. Had not menstruated for ten months.

Physical examination showed marked emaciation, the pectoral muscles had almost dwindled away, and each rib could be readily outlined by the eye. Left side of the chest was somewhat more prominent than the right. Percussion gave dullness over superior and middle lobe anteriorly on right side, with somewhat of the tympanitic quality over the inferior lobe. Left side hyperresonance of both lobes. Vocal fremitus increased on right side. Respiratory murmur of upper and middle lobes on right side very feeble, bronchial over lower lobe. On left side diminished inspiratory murmur, with prolonged expiration. No râles, cough entirely absent, but some dyspnœa. Heart's action irregular, second sound slightly accentuated, and there was present a soft systolic, basic murmur propagated along the large venous trunks. The diagnosis of caseous pneumonia with boulimia was made, and the patient put upon an exclusive milk diet (4 ounces of milk with half ounce of lime water every three hours), and sodium bromide ʒss, morning and night. After four days she stated that the quantity of milk was insufficient, and I allowed her six ounces (mixed with six drachms of liq. calcis) every three and a half hours, a teaspoonful of sulph. of magnesia every second morning for constipation. At the end of two weeks she stated that the feeling of weight and distress in her stomach had almost ceased, that she slept better, and although often tempted to eat whatever she saw on the table, was able to control herself. She begged to have something in addition to milk, and was allowed stale bread with underdone beef once a day, and some ripe fruit in the morning. Six weeks later her menses appeared again, the flow lasting two and a half days, she had gained three pounds in weight, and felt much better in every way. The bromide, which had been reduced to ʒss at bed hours, was now discontinued, and Blaud's pills with the $\frac{1}{48}$ grain arsenious acid t. d. ordered. Her diet was gradually and cautiously added to, being allowed milk with toast and a soft-boiled egg for breakfast, roast steak or fish, with a vegetable and bread and butter for dinner, a glass of milk in the afternoon, and milk or tea, with a chop and stale bread, for tea. In four months (May) she had gained considerably in weight, when suddenly her "feasting propensity" manifested itself again. When she next came to my office I at once perceived a great change in her manner. At first she was sullen, saying she had dyspepsia again as bad as when she first came to me, and knew that she could not get well. A few kind words at once showed her impressionable nature; she burst into tears, and crying bitterly, said that she was not worthy of my further attention, that she had disobeyed my directions, eaten everything and as much as she could get for the last two weeks, and suffered in consequence, as at first. She could not sleep, and feared her reason was giving way. I ordered the valerianates of quin. ferri et zinci with a full dose of hydrobromate of hyoscine at bed-time, but with no benefit. She continued nervous and melancholy, and some days afterwards got out of bed at four o'clock a. m. and wandered to the Park, her parents not knowing where she was, and being in great dis-

tress about her. In the latter part of the following month I detected evidence of softening in the right upper lobe; she had no cough, but fugitive pains under the clavicle, extending to back. I ordered tr. iod. with opium locally, and gave her the carbonate and iodide of ammonia in solution of the acetate every four hours. Her appetite now began to fail; in about a week she could scarcely be persuaded to take any nourishment; softening proceeded rapidly; tubercular deposits took place, hectic fever came on, and she died of pulmonary obstruction, July 30, *cough being entirely absent to the end.*

1949 *N.* 13*th St.*

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

Adjourned meeting, December 17, 1886. The President, Dr. John B. Roberts, in the chair.

Dr. Daniel Longaker read a paper entitled

Some Points in the Treatment of Inflammation and Abscess of the Breast.

Fully convinced of the correctness of the principles of treatment of mastitis, lately advocated by P. A. Harris* in such an able manner, I at once determined to carry into practice his teaching. After a trial extending over some eighteen months, and having, during that time, had unusually excellent facilities for observation, I feel ready to advance an opinion as to its usefulness. To say that this is most favorable, but partially expresses my feelings.

When a large class of patients continues to be daily treated in a manner so at variance with sound principles and logical conclusions, based upon well-known facts, no apology is needed for entering again upon the discussion of the subject.

If the methods so commonly employed in the treatment of these patients were harmless, and did not distinctly aggravate matters, they might be regarded with composure. But the continued application of the child to an inflamed breast is quite harmful. So are manipulations, frictions, suction by means of pumps, shields, and any measure calculated to remove the secretion, from fear that if the distension be not relieved an abscess will form. Prof. Wm. Goodell† is authority for the statement that gathered breasts do not occur after still-born children. This accords entirely with my own experience.

The liability of trouble at subsequent confinements in women who have once suffered from this disease, is admitted. Yet most excellent results followed in two such cases where no attempt was made to use the susceptible organ. In both these instances the sound breast alone was used during the period of lactation.

Our positive knowledge of the etiology of mastitis has been advanced by recent studies and experiments of Baum.* He says: "There is no doubt that the described organism, diplococcus, introduced into the cellular tissue, has the power of reproducing itsef, and by extension, cause infiltration and suppuration."

It is to be hoped that more extended studies than have yet been made will be instituted in regard to the rôle of this micrococcus. It may be the agent which, finding its way into the lymphatics by an erosion or fissure of the nipple, finally reaches the interlobular and interacinous connective tissue, there to develop to an alarming and destructive extent. The danger of mastitis in fissure of the nipple is a generally recognized and a real one, whether it be due to the microbe or not.

The intensity of the symptoms of mastitis usually depends upon the severity and extent of the disease. Its onset is distinct; with a decided chill, or repeated chills, a marked elevation of temperature, and the presence of a very painful, swollen and tender area in one of the breasts, the diagnosis is a very simple matter.

If nursing, at least upon the affected side, be at once interrupted, if all manipulations of the gland be interdicted, and if, in short, absolute and complete rest be secured, the disease will terminate, in the large proportion of cases, by resolution. According to Winckel,† 136 cases, in the Dresden University, resolution took place in ninety-one, or sixty-seven per cent. I believe that even better results than this may be achieved.

If these correct principles are not followed, the termination will be, in the majority of cases, suppuration, often lasting many months.

It is but just to state that Lusk‡ and King§ recognize the necessity of suspension

of suckling from the inflamed breast. Still, both allow other manipulations equally, if not more, injurious. The statement of Billroth* appears illogical when he says: "I believe Roser is entirely right in assuming that milk retention is not a *cause*, but a *consequence* of mastitis;" and then adds later on: "If the inflammation be in the gland itself, nursing at breast on the affected side is best suspended; but if the breast becomes much distended, it is emptied by means of a breast-pump." He is opposed to manipulation because it may increase the inflammation.

My experience has fully demonstrated that the bandage is capable of overcoming the pain that might result from distension. This should be two and a half inches wide and 20 yards long. A bandage fourteen yards long will be sufficient, according to my experience, of some cotton or flannel, or what I have found particularly applicable, the so-called "Globe antiseptic wool." The only objection to the latter is its high price. By means of this material the inflamed breast is covered, and it is then closely, evenly, and in a sufficiently firm manner, enclosed by figure-8 turns of the roller. On the healthy side the nipple may be allowed to be exposed, if it be considered advisable to apply the child on that side.

Disagreeable pressure on the shoulders is avoided by interposing a layer of the wool. If, during the application of the bandage, the patient be repeatedly questioned as to its being too tight, disagreeable experiences and too much pressure will be avoided.

Still more complete rest may be secured, if in addition to this the patient be confined to the dorsal position. Quinia, salines, opiates, are all of secondary importance to this principle of rest.

Since the adoption of this plan in the Lying-in Charity, the occurrence of abscess has been quite rare, though a number of cases of marked inflammation were encountered. In the service of my colleague, Dr. C. J. Wilson, the same plan is followed, and his opinion of its value is fully in accord with my own.

The general disturbance, usually soon ceases, and the local condition improves. Usually the bandage is removed and reapplied on the following day. Occasionally it remains in situ 48 hours. In from eight to ten days the disease has ordinarily completely subsided, and the breast is again used.

Dr. Hiram Corson† is a strong advocate of cold in this disease. He depends upon this for the removal of painful distension, and does not empty the breast by means of pump or any other manipulations.

The treatment of fissures of the nipple is also a very important matter. Much may be done to prevent their occurrence if, before delivery, accumulation and desiccation of secretions upon the nipple and aveola be avoided by frequent bathing with warm water.

For slight conditions the tinct. benzon. co. has proved of much value. It is applied to the fissured surface after thorough cleansing. The use of Needham's shield is advantageous. In severe and otherwise intractable cases rest from lactation for a few days will accomplish a cure.

During the last year, both in hospital and private practice, I have had repeated opportunities for observing the results of inflammation treated by other plans. In all of these the breasts have been in various stages of destruction—honey-combed and riddled with sinuses and fistulous openings which have been discharging for months. The treatment of such cases is unsatisfactory, unless very radical measures are adopted. It is surprising how extensive, from the onset, many of these cases are. I am convinced that if their true nature were more fully appreciated, the result would always be much better.

Even when, as should always be done so soon as fluctuation or the presence of an œdematous and reddened area make it certain that suppuration has occurred, a free opening is made and drainage-tube used, the result is sometimes disappointing. The relief is only partial and temporary, and in a few days the breast grows very painful, and in one or more places gives evidence of the formation of fistulous openings.

When this is about to take place the original incision of one-half inch should be enlarged, the finger introduced, and the walls intervening between the various foci of suppuration broken down. In this way the entire extent of the disease is converted into a single cavity, and this, under the influence of drainage, antiseptic irrigation and dressings, is enabled to heal in a short time. A process which might continue for a long time is thus terminated within the limits of a reasonable period.

"It need not be wondered at," says Billroth, "that these patients, after six or eight operations, lose all confidence in the doctor or in his art."

The following conclusions are justified:

*Billroth, Handb. v. Frauenkrank., p. 15.

†Amer. Jour. Obstet., Jan., 1881.

1. Milk retention is not a cause of mastitis.

2. Milk retained in an inflamed breast does no harm.

3. Any effort to remove the secretion increases the intensity of the inflammation by stimulating the functional activity of the gland.

4. The fundamental principle to be observed in the treatment of mastitis is *rest.* This will prevent suppuration.

5. In suppuration early incision, under antiseptic precautions, and drainage, are to be strongly urged.

In the discussion which followed the reading of Dr. Longaker's paper, Dr. James B. Walker said: "When mammary abscess threatens, give at least *partial* rest. Fissured nipples nearly always anticipate abscess; and these are due, often, to too frequent nursing during the early days of the puerperal state before lactation is established. Because of this, it has become a habit with me to order the infant put to the breast every *four* hours during the first sixty hours after delivery, and after lactation is thoroughly established every *two* hours. Sore nipples indicate either an insufficient quantity or an improper quality of milk, and every alternate feeding should be artificial, this giving the nipple *eight* hours rest instead of *four.* If a stinging sensation occur in the breast, just as the child finishes nursing, give the breast partial rest by feeding the child artificially every alternate time and the pain will soon disappear. For the engorgement of the breasts, on the third day after delivery, at the beginning of lactation, I have used camphor stupes with benefit and comfort to the patient."

Dr. Edward R. Stone was recalled to a patient ten days after delivery, and found symptoms of threatened mammary abscess. He applied adhesive strips and gave the gland complete rest; in three days all bad symptoms had disappeared, and lactation was resumed. For fissured nipples he has used a two per cent. solution of cocaine, having the parts carefully washed before the child was put to the breast, with good results. He has also used camphor and chloral, equal parts, very satisfactorily in some cases.

Dr. Clara Marshall mentioned a case of fissured nipples where she had used lead shields over the nipples with advantage.

Dr. Walker said that in one case of fissured nipples he had the patient to wear the Wansbrough lead shields during the intervals of nursing, and the fissures soon healed.

Dr. Emma Musson has used lead shields in one case. The result was very satisfactory. The shields were kept in a solution of boric acid while the child was nursing.

Dr. Amy S. Barton has used a solution of cocaine for fissured nipples, applied on cotton, having the part carefully washed before the application of the child.

Dr. Mary Willits has used subnitrate of bismuth in several instances with good results. In one case the fissure was very deep, giving rise to severe pain and considerable bleeding at each nursing. Various remedies were used without any benefit being derived. On using bismuth, and having the child to nurse through a rubber nipple shield, thus giving the parts more rest, the fissure healed.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated meeting, January 12, 1887.

The President, J. Solis Cohen, M. D., in the chair.

Dr. H. A. Wilson read on behalf of Dr. John B. Roberts the report of

A Case of Suprapubic Lithotomy, followed by Death from Perforating Ulcer of the Stomach.

The following case of removal of stone from the urinary bladder by the suprapubic or high operation is reported as proving the position which I have so long insisted upon, that this operation is easily accomplished, and is free from many of the dangers of the lateral perineal operation.

C. H., aged sixty-three, applied to me for relief from frequent urination and other bladder symptoms, and was sent to the wards of the Pennsylvania Hospital. Upon the introduction of the lithotomy sound, it was easy to discover the presence of a stone. When the catheter was used, the stone was struck before any urine was drawn from the bladder, apparently proving that the calculus lay close behind the prostate gland. The patient was a very fat man, with poor circulation, and evidently a bad subject for etherization or operation. The urethra was large and easily distended. It therefore seemed to me proper to attempt the removal of the stone by the rapid crushing method.

With this object in view, I had him frequently dilated with large bougies, in order that the urethra and bladder might become tolerant to the contact of instruments. Subsequent to this preparatory treatment, I

made an attempt to crush the stone with a lithotrite, expecting to evacuate the fragments by the ordinary method of Bigelow. Repeated efforts proved the impossibility of seizing the stone, either because it was too large to fall into the grasp of the blades of the instrument, or because it was encysted behind the prostate gland. Even with a finger in the rectum, and with the jaws of the lithotrite turned downward, seizing the stone was impossible.

As the man's perineum was deep, and as I believed that the perineal operation was inferior to the suprapubic one, because of the liability of hemorrhage, of injuring the seminal ejaculatory apparatus, and also because of the supposed size of the stone, and its possibly encysted character, I determined to perform the suprapubic operation.

After etherization, a rubber bag to which was attached a long tube, was placed in his rectum, and filled with about twelve ounces of warm water. The bladder was afterward filled with six or eight ounces of a weak solution of bichloride of mercury. A three-inch incision was then made in the median line through the skin and a depth of nearly two inches of adipose tissue. The muscles were then separated, and the tissue torn through with my finger until I came upon the distended bladder. By means of a curved needle I passed a string through the top of the bladder, and brought both ends out of the wound to serve as a handle by which the bladder could be held up close to the surface. A longitudinal incision of about an inch in length was then made in the anterior wall of the bladder from above downward. The water immediately escaped from the bladder, and on the introduction of my finger I felt a large flattened stone lying in the lower portion of the organ, but not encysted. After some little difficulty, the calculus was seized in ordinary lithotomy forceps and drawn out of the bladder, the wound in which was then closed with interrupted catgut sutures. The muscles were brought together by buried sutures of catgut, and the integument subsequently closed in the same manner. A drainage-tube was carried in at the middle of the incision, and pushed down into the space between the anterior wall of the bladder and the pubic bone. The edges of the wound were finally sprinkled with powdered iodoform, and the ordinary antiseptic dressing of gauze and corrosive sublimate applied. A hard-rubber catheter was left in the urethra in order to drain the bladder. At the end of twenty-four hours it was found impossible to keep the catheter in the bladder because of the pain which it gave the patient. Accordingly his urine was drawn at frequent intervals by means of a catheter similar to that originally introduced, but it was very difficult to keep the dressings properly applied and avoid their becoming soiled by the urine.

Three days after the operation the wound seemed well united along the surface, and a couple of days later the drainage-tube and two of the sutures were removed. Dribbling of urine soon began to occur through the opening left by the withdrawal of the tube. This continued until eight days after the operation, upon which day the last suture was removed. On the evening of the same day the patient vomited about six ounces of blood, and during the straining of the vomiting on that day, or on account of the sitting up in bed a few days later, the wound became gaping throughout its entire length. The edges of the re-opened wound were again brought together by sutures of silkworm-gut and shot.

From this time forward the man's general condition was bad, although the wound gradually closed, except superficially, and all dribbling of urine from the wound ceased. In fact, he seemed to have recovered from the local effects of the operation, and to have left merely the deep wound through the skin and superficial fascia. Here the granulations were sluggish, and the repair of the opening in the fatty tissues and skin were inactive. He was, however, able to pass his urine normally through the penis, and so far as urinary symptoms were concerned was in a very comfortable condition. There persisted, however, nausea, a dull, uncomfortable feeling of pain in the epigastric region, and a total want of appetite. I was unable to make any definite diagnosis as to the meaning of these symptoms. Disease of the liver or stomach were the suggestions which came to mind.

Two months after the operation he suddenly suffered intense pain in the epigastrium, and immediately went into a condition of profound shock, from which he never reacted. A few days before this time he had been sitting up in a chair every day, and the wound in the abdomen was almost closed. He had no trouble in urinating, and was very comfortable, except for the epigastric pain and the great weakness.

The post-mortem examination showed a large gastric ulcer the size of a silver dollar, which had caused perforation of the walls of the stomach, and had allowed its contents to escape into the peritoneal cavity. The cause

of the vomiting of blood, of the impaired nutrition, and of the constant pain which he suffered for many weeks before death, was, therefore, shown to be a gastric ulcer, probably present before the time of operation, but latent in regard to symptoms.

The ease with which the suprapubic operation can be performed, due largely to the distention of the rectum and bladder by the fluid forced into them previous to making the first incision, was clearly demonstrated in this case. The facts that union of the bladder wound and early restoration of the functions of the bladder in regard to urination readily occur after the high operation for stone, and that wounding of the peritoneum is easily avoided, make this method of removing vesical calculi very satisfactory. The unfortunate death of the patient from disease of the stomach does not in any way vitiate the results of the operation; for, although the patient had not recovered sufficiently to be discharged from treatment, still the operation had effected the results which I sought.

Dr. J. Solis Cohen presented

A Series of Three Epithelial or Pseudo-Membranous Casts of the Tonsils and Palatine Folds of a Case of Diphtheria.

The patient is an adult, and has exhibited no symptoms of a constitutional infection. The local disease was limited to the tonsils and palate: one tonsil became parenchymatously enlarged and underwent suppuration. The abscess was opened twice. At present there is an additional abscess in the upper portion of the palate. There has been no complication in the case except from difficulty in deglutition, so great that for forty-eight hours the patient had to be nourished mainly by the rectum. Two days ago there was brought to me a thin sheet of false membrane, which was an accurate mould of the tonsil and palatine fold. Yesterday a similar mass of desquamation, having much the same shape, was brought; and this morning a third mould had been thrown off. The appearance of the second cast closely resembles a cast of the interior of the larynx and trachea, and could readily have been mistaken therefor had there been any laryngeal complication. Manipulation, however, demonstrates that it has sheathed the tonsil and one of the palatine folds.

The point to which particular attention is called is the physical resemblance of these patches to the desquamated epidermis in scarlatina.

NEW YORK ACADEMY OF MEDICINE.

Annual meeting, January 6, 1887.

A. Jacobi, M. D., President, in the chair.

Dr. Jacobi was re-elected President, and Dr. William H. Draper was elected Vice-President.

Dr. L. Emmet Holt read a paper entitled

The Antiseptic Treatment of Summer Diarrhœa.

The conclusions to which he arrived were that summer diarrhœa is not to be regarded as a disease dependent upon a single morbid agent. The promoting causes are many, such as heat, improper feeding and surroundings, dentition, etc. The immediate cause is putrefactive or fermentative changes taking place in the stomach or bowels in food not digested, which changes often began outside of the body. These products may act as systemic poisons, or they may cause local inflammation and changes in the intestine. The diarrhœal discharges, at the onset at least, are salutary. Opiates, especially in the beginning, may do harm. It stops peristalsis and cleansing of the bowel. Salicylate of sodium has a marked influence in restoring healthy action in the stomach and intestines. Naphthalin, though not equal to this drug, is certainly of great value, particularly in cases of long standing.

The author had treated 300 cases by bismuth and Dover's powder, frequently but not always preceded by castor oil, with the estimated result of 52 per cent cured, 27 per cent. improved, 18 per cent. unimproved, 7 per cent. died. Of 81 cases treated by salicylate of sodium, 84 per cent. were cured, 7 per cent. improved, 7 per cent. unimproved, 1 per cent. died. He had obtained good, but not equally good results from naphthalin. He had also used bichloride of mercury and resorcin. The drugs employed for summer diarrhœa which had held their own during the past fifty years were now recognized to be antiseptics.

Dr. Wilcox and Dr. Peabody related cases of chronic diarrhœa in adults of long standing cured by naphthalin. The views of the author were generally endorsed by those who discussed the paper, Drs. A. H. Smith, R. Van Santvoort, J. C. Peters, W. M. Carpenter, and the President.

—Dr. S. L. McKeown, of Dallas, Texas, relates in *Daniel's Tex. Med. Jour.*, a case of malarial hæmaturia with obstinate vomiting successfully treated with hypodermatic injections of the $\frac{1}{35}$ of a grain of strychnia.

Editorial Department.

Periscope.

Hysterical Affections.

Dr. F. T. Thistle reports these cases in the *Lancet:*

Case 1. Harriet B——, aged forty, unmarried, dressmaker, was admitted into the hospital on February 22, 1883. She had always been a very emotional subject. Three years before admission, the left breast was removed at the Middlesex Hospital for scirrhus. She had been in bed eleven weeks before admission. She complained of pain in the left thigh and leg; there was no swelling; the muscles were slightly wasted; the left lower limb was completely paralyzed, and she could not move it in the bed; there was partial anæsthesia of the whole limb, most marked on the inner side of the thigh; she was anæmic in appearance. She was put on strychnine and iron; the leg was faradized daily, and blistered in a few places with the thermal hammer. In three days she was walking on crutches, a few days later with a stick only, and soon was able to walk without any support at all. She had some difficulty at first in getting up and down stairs, but was made to practice it several times in the day. She gradually improved in health and strength, and was discharged on May 21, when she could walk several miles a day.

Case 2. Mary W——, aged twenty-five, formerly a servant, was first seen by me in consultation with Dr. Wills about the middle of February of last year. She had been in bed for five years, and had to be lifted from one bed to another. She was a most pitiable object, emaciated, peevish, unable to stand or walk or feed herself. She could move her legs in bed, but in getting her out of it they gave way under her, and she would have fallen if not supported. I offered to take her into the hospital, telling her that she would get perfectly well. She objected very much, and said she did not want to get well. After much persuasion she consented to come in, and was admitted on February 24th. On admission I ordered her milk and beef-tea at first, as she had taken nothing but slops for some time. She was faradized and rubbed every day. On the third day I ordered her a mutton chop; this she obstinately refused to eat, saying she could not swallow it. On being informed of this by the nurse, I went up into the ward, cut the chop into small pieces, and insisted on her eating it, threatening to apply the battery if she would not do so. After a good deal of trouble she ate the whole of it, with some bread and a cup of milk. After this we had no further trouble about her food, and she was put on a liberal diet. On the fifth day she was out of bed, and able to walk a little when supported on each side by a nurse; a few days later she could walk with crutches in the garden. She gradually gained flesh and strength, and was discharged from the hospital seven weeks from the date of admission, able to walk two or three miles in the day. She then went for a few weeks to a convalescent home in the country, and returned much benefited by the change.

Case 3. Mary T——, aged twenty-one. I first saw this patient with Dr. Eales on July 11, of the present year. She had been in bed or on a couch for three years, and was considered by her friends to be suffering from heart disease and consumption. She was very emaciated, and could not stand without being supported; her breathing was rapid and noisy, and she jerked out her words in a spasmodic manner when answering questions, which she rather whispered than spoke. She complained of pain over the region of the heart, which was beating quickly and feebly; the sounds were natural; breathing jerky, but nothing abnormal about the lungs. We recommended her friends to send her into the hospital, and promised that she would get quite well. She was admitted under my care on July 13. Her weight on admission was 67 pounds. She was faradized and rubbed every day, given as much good nourishing food as she could be made to eat, and ordered cod-liver oil and iron. As in the previous case, she was got out of bed, and walked at first with support, and very soon by herself. A small blister was placed over the region of the heart, which removed the pain she complained of. The breathing soon became natural. She rapidly gained flesh, strength, and weight. In a fortnight she was able to take good walks. She was discharged on September 16, and sent to a convalescent home on the Moor. Her weight on leaving was 80 pounds, having gained 13 pounds in rather more thon two months.

The above cases are examples of many to be met with in practice. Whatever name we may apply to them—real, ideal, hyster-

ical, or neurotic—they are all of them very amenable to treatment, are extremely interesting to watch, and amply repay in their satisfactory termiuation the time and trouble devoted to them.

Terpine in the Treatment of Neuralgia.

Dr. Ducroux, in a paper recently read before the Société Médico-pratique, of Paris, described some cases showing the good effects of terpine in neuralgia. The first was that of a woman, aged 47. Two years before, she had been attacked with neuralgia, consequent on occupying a damp house. Sulphate of quinine, and afterwards aconitine, gave temporary relief. On February 15, 1886, she was suffering from constant neuralgia on the right side of the lower jaw, in the right cheek and temple. There was also pain in the supra-orbital notch, the mental foramen, and in the occiput. The patient complained of a constant feeling of heaviness in the head, and of cold in the right side of head. Terpine (.60 centigramme) was given in three pills between meals, during three days. On February 19 considerable relief was obtained. The pains and the feeling of cold had disappeared, and also the heaviness of head, which had persisted for two years. The pains having returned in a few days, terpine was again administered in the same manner on February 25. The pains ceased, then re-commenced, but in a milder form, and without any heaviness of the head. Terpine was again given on March 8. Neuralgia having again come on, doses of .80 centigramme were administered in four pills, beginning on March 10, and being continued for three days. During the month of April, these doses were repeated at intervals. At the end of that month, the back of the head was still sensitive, but all other pains had ceased. At the beginning of May and June, terpine was again administered, the pains having re-appeared. On June 15, the patient was able to go out without extra covering on the head. Dr. Ducroux is of opinion that the patient may again be obliged to have recourse to terpine, as the neuralgia shows a tendency to recur, though in a milder form. The therapeutic effect of the terpine seems to cease after a few days. In cases of obstinate neuralgia it might be advisable to give it for three days every week. The second case was that of a married woman, aged 35. At the age of 22 she had intermittent fever. From the age of 13 or 14, she had suffered from headache from time to time, and when she was 22 she had intermittent fever. Menstruation had ceased for six years. A week ago she was attacked with pain in the right side of the head, differing from her habitual headache. The pain, which gradually increased, extended in front, around the ear, and over the temple and cheek, and behind, over the mastoid region. There was also pain in the external auditory meatus. The pains were accompanied by a humming in the ears. Terpine (.60 centigramme) was given in three pills, to be taken between meals. On April 29 the pains had disappeared, but the humming in the ears continued; .50 centigramme of sulphate of quinine was administered during three days. This had no effect. A few days before May 17 the humming in the ears diminished, and took a different form. The sound in the ears was no longer that of humming, but of running water. The patient could neither hear herself nor others speak. Terpine was again administered in the same way. The sounds in the ears diminished and completely disappeared two or three days after the last dose. Dr. Ducroux believes that the disappearance of the pains was due to the use of terpine, and that it had some effect upon the sounds in the ears. The third case was that of a man aged twenty-three. Fifteen years before he had suffered from bronchitis, with hæmoptysis. In May, 1885, he was attacked with severe pain over the right eye, in the supra-orbital notch, and about the occiput. A blister was applied to the temple, and dressed with one centigramme of morphine; terpine (.60 centigramme) was given in the way already described. The first morphine dressing did not relieve the pain, but the second, applied the following evening, was more effectual. The patient had then taken three terpine pills. As the improvement continued, only eight pills were administered in the three days following the second day. The neuralgia was completely cured. Dr. Ducroux attributes this result to terpine, as the morphine application produced no effect.

Scarenzio's Treatment of Syphilis.

Scarenzio's treatment, it may be remembered, consists in the subcutaneous injection of calomel, held in suspension in glycerine (10 centigrammes of calomel to one of glycerine). Several injections are given, to the amount of 40 centigrammes in all, the treatment lasting about four months. The plan is said to be very effectual, not only curing the symptoms appearing in the progress of the disease, but preventing their return. M.

Balzar, wishing to try this treatment at the Lourcine Hospital, Paris, but fearing the irritating action of glycerine, and the great pain which it causes, determined to use vaseline oil as a vehicle for the calomel. Two hypodermic injections of the pure oil were first tried, which proved absolutely painless, and left behind them neither irritation nor induration. A severe case of syphilis was then chosen. The patient was a young woman, aged nineteen, who had been suffering from the disease for about five months, and was in the sixth month of pregnancy. Large mucous patches covered the labia majora, and the posterior portion of the anus; there were also some on the left tonsil. She had, besides, general roseola, with large maculæ, and an abundant papulo-squamous eruption on the abdomen and the lower limbs, with general enlargement of glands. The patient had been for some time under the following treatment: Two Dupuytren's pills daily, with two spoonfuls of the syrup of iodide of iron; compresses, moistened with Van Swieten's fluid, diluted with distilled water, applied to the vulva during the night; cauterizations, with a 1-20th solution of nitrate of silver; gargles of chlorate of potash; and baths. All this had been absolutely without benefit. On October 4, a first injection of 2½ centigrammes of calomel, in 50 centigrammes of vaseline oil, was given in the back. No pain was caused by the injection. On the following days, a small, soft, slightly painful swelling appeared at the seat of injection. On October 11, another injection of 5 centigrammes of calomel was given in the lumbar region, and, in a few days, the swelling was as large as a hen's egg. At one time the formation of an abscess was feared, but, in about ten days, the indurated swelling began to subside. Meanwhile, the cutaneous affections which had hitherto proved so refractory under treatment, had rapidly improved. Already on October 25, the roseola, together with the patches on the vulva, had disappeared; of the latter there remained but a dry, violet-colored macula. The general state was excellent, and the pregnancy was following its normal course. On November 18, the amelioration still continued, and the induration at the seat of injection had shrunk to two-thirds of its original size.

Hysterical Paralysis Following a Dream.

At a meeting of the Biological Society of Paris, M. Féré related the following interesting case:

The patient was a young girl, aged fourteen, who for some time had grown rapidly, and whose menstruation had stopped. One night she dreamed that men were chasing her about the Place de l'Odéon, in order to kill her. She managed, with much effort, to escape, but, on waking up, felt extremely fatigued. On the following day, her legs gave way under her. The dream was repeated several nights in succession, and even continued while awake. Every morning the weakness of the legs increased. A few days later, on attempting to go up stairs, she fell, and was unable to rise; she was found to be paraplegic. In this case, M. Féré called especial attention to the fact of paralysis following the dream. In some cases, so-called psychical paralysis admits of a pathogenic interpretation different from that generally accepted since the investigations of Russell Reynolds and Charcot. It is, in fact, admitted that this kind of paralysis occurs through idea or suggestion; that is to say, the motor disturbance is only manifested after mental symptoms. This theory has even been applied to paralysis from traumatic shock. The circumstances which preceded the appearance of paralysis in this case seemed to favor the theory of paralysis from exhaustion. In reality, the weakness of the limbs came on gradually under the influence of fatigue, caused by exhaustion of the motor centres, resulting from a rapid succession of volitional discharges not followed by actual movements. All dreamers are familiar with the muscular fatigue following dreams of movement. Moreover, the same patient offered another example of paralysis through fatigue, when she lost the power of phonation after an analogous set of phenomena. In a fit of excitement caused by enforced repose, the patient gave vent to a violent torrent of words, which continued for two hours, after which she fell asleep. On awakening, she had complete aphonia, due, in M. Féré's opinion, to fatigue. The aphonia was accompanied by difficulty in writing, which has rarely been observed in hysteria. Cure was effected by means of passive movements. M. Féré added that, by exciting dreams of movement in hypnotizable subjects during natural sleep, he could induce analogous paresis, accompanied by dicrotism of step similar to that in the patient, and due to a predominance in the action of the gastrocnemius, causing the toes to touch the ground before the heel. In a certain number of cases, the so-called psychical paralysis is brought about by exhaustion following prolonged cerebral fatigue, and not by the subjective representation of fatigue or of paralysis.

"Dead Space" in Certain Chemical Reactions.

The most important discovery now spoken of in Berlin medical society is that of Professor Liebreich, who only a year ago presented us with the new basis for ointments. His latest discovery is more in the sphere of pure chemistry, but it is also interesting to physicians. Professor Liebreich observed that when reaction takes place only some time after mixing certain liquids together, it does not occur throughout the whole liquid; in some parts a space is left, in which no reaction is seen, and this he calls the "dead space." He has observed the same in several reactions—for instance, on mingling sulphuric acid, iodic acid, and starch together, or hydrate of chloral with carbonate of sodium, or chloride of gold, sodium lye and sugar, and in many other cases. The so-called "dead space" is not always the same, but varies according to the kind of vessel into which the liquids are poured. If, for instance, narrow tubes are used, the "dead space" is very small, while in capillary tubes no reaction whatever takes place. If the liquids are poured into closed vessels with rigid sides, the "dead space" cannot be seen, but if the closed vessels are of membranous structure, it may be observed. Thus, for instance, in a prepared rabbit's bladder the "dead space" is at the top and bottom, whilst the reaction takes place in the middle in the shape of the yolk of an egg. If a piece of gut is taken and divided by means of little rings into a number of small compartments, and if one of the above-mentioned liquids is poured into it in each of the compartments, the reaction is seen taking place in the middle, while at the top and bottom there is a "dead space." As the "dead space" depends upon the size of the vessel, it may be inferred that for every chemical mixture yielding a reaction, proportions can be imagined in whieh reaction ceases. The laws of reaction, therefore, are dependent on the space in which the effect takes place, and hence these observations have an important bearing on the organism. In testing the effect of certain medicinal agents, not only must their chemical constitution be taken into account, but the laws governing their reaction in large and small spaces respectively.

A Newly Discovered Substance in Urine.

Dr. Leo's researches on sugar in urine are interesting, and tend to correct the commonly accepted views on the subject. Professor Scheibler, a chemist well known for his researches on sugar, has observed that the determination of the quantity of that substance contained in a liquid gives different results, according as it is done, by Trommer's method or with the polariscope. As sugar nowadays is exclusively dealt with according to the degree of polarization, this fact is of enormous value in trade. Scheibler has isolated a substance that is more powerful in that respect than grape-sugar. Dr. Leo's researches yield analogous results, though in a different field. He has examined a great quantity of diabetic urine after three different methods, namely, Trommer's (alkaline solution of copper); by fermentation; and with the polarization apparatus. In many cases the results agreed, while in others there was a considerable difference. He succeeded in isolating a substance corresponding in its chemical composition to grape-sugar, and also a carbo-hydrate differing considerably from grape-sugar, and turning the plane of polarization to the left. The power of reduction of this newly discovered substance is to that of grape-sugar as 1 : 2.48. Dr. Leo found this substance in three specimens of diabetic urine, but it was absent in normal urine, although a great amount was examined for that purpose. From this it may be concluded that the substance does not originate outside the organism, and that it is a pathological product. The theory of Dr. Jaques Meyer, of Carlsbad, that it may be connected with obesity, is negatived by the fact that of the three persons in whom this substance was found only one was corpulent.

Imperforate Os Uteri—Vicarious Menstruation—Operation.

Dr. R. C. Prewitt thus writes in the *Mississippi Valley Med. Mo.:*

Some time ago Mrs. B., aged twenty-seven years, came to me for treatment, stating she had hemorrhage from the lungs, which occurred about every two weeks; that her bowels would swell about the same time, when she would have a slight menstrual show. She was very anæmic, and from her statement and general condition I concluded it must be a case of vicarious menstruation, and believing some obstruction to exist about the mouth of the womb, I told her a specular examination would be necessary. She readily consented, and I found there was no os uteri, so to speak, but instead a small opening three-quarters of an inch to the left of the median line. This was too small to

admit the smallest size bougie, and barely large enough to admit a knitting-needle. I stated to her that the opening was too small to permit the free outpouring of the menstrual fluid, hence the periodical spitting of blood, and the remedy would be to enlarge the opening. I did this by first introducing a grooved director, and then with a sharp-pointed bistoury cut one-half inch in the direction of where the os uteri should have been. This caused some hemorrhage, which however was easily controlled. I then inserted a sponge-tent, saturated with vaseline, which I allowed to remain over night. On the following morning I replaced it with another, and so on until the third day, washing the vagina thoroughly each time with carbolized water. The fourth day I changed from vaseline to carbolized oil, which I continued for two weeks, when she came properly unwell for the first time in her life, never having had more than a show. There was no more swelling, no more spitting of blood. I kept her on wine and iron tonics for two months, at the same time requiring her to inject the vagina with at least a gallon of warm water every day or two. It has now been six months since the operation, and my patient has been perfectly regular every four weeks, and sufficiently free. I thought of using the uterine dilator, but the opening was too small to admit of its introduction, so I decided to use the knife. There was no evidence of there ever having been an os tincæ, as there was no opening and no cicatrix. The opening which I mention I believe was a fistulous one, proceeding from the menses collecting and causing suppuration, and consequently if there had never been a menstrual discharge in the uterus there would never have been an opening.

This case was a very interesting one to me, and though similar ones may have frequently occurred, this is my first in a practice extending over twenty-four years.

Pilocarpine as a Galactogogue.

The remarkable effect of pilocarpine on the secretions, particularly of the skin and the salivary glands, has long been known. It remained to be seen whether this influence was not likewise exerted on the secretion of milk, since the mammary glands resemble, in certain respects, the sudoriparous glands. Some writers have incidentally mentioned the action of pilocarpine as a galactogogue; but, from a practical point of view, nothing seems to have been published on the subject. For several years M. Chéron has carefully studied the effect of pilocarpine on skin diseases, and he has discovered that the therapeutic action of the drug can be produced in smaller doses than are necessary to stimulate the activity of the salivary and sudoriparous glands. The discovery of this important fact enabled him to employ pilocarpine in subcutaneous injections, without risk to the child, in the case of nurses whose milk-secretion had ceased. The following was his method of proceeding in nine cases, which, with one exception, turned out satisfactorily: Five centigrammes of the nitrate of pilocarpine were injected as soon as the milk became scanty, whether this took place suddenly or by degrees. The injection was repeated every day. Under its influence the skin of the face, and afterwards that of the body, became hot for a few moments, but there was seldom any moisture. It is essential to success not to produce diaphoresis. If the scantiness of secretion has existed for some time, ten or twelve injections are required; on the other hand, if it has come on suddenly, two or three will suffice. The treatment had no ill effect either on the nurse or the nursling.

Arthropathia Tabica.

Much has been said lately about the occurrence of joint-disease in tabes. In all the cases hitherto reported, the joints of the extremities have been affected; recently, however, Dr. Krönig brought before the profession in Berlin examples of spinal disease occurring in tabes. He reports three cases of patients who had suffered from tabes for three years, and in whom the characteristic features of the disease were more or less distinctly present. In three cases the spine had been fractured by injuries quite inadequate to produce such a result in a healthy body; it appears fair to conclude, therefore, that the bones had been rendered unnaturally fragile by the disease. Dr. Krönig therefore suggests that measures should be taken in all cases of tabes to prevent such an accident. Professor Leyden and Dr. Beely expressed warm approval of this proposal. Dr. Leyden stated that he had seen a jacket put on in a case of tabes, and also in one of paralysis spastica, for the purpose of counteracting weakness of the legs. If the disease of the spinal marrow reaches high enough for the muscular system to be affected, it must be of the greatest benefit to immobilize the lower part of the trunk. Dr. Beely thinks that a jacket should be used as a means of preventing vertebral disease.

Peptone.

Dr. Labastide, in the *Gazette des Hôpitaux*, publishes notes of cases showing the good effects of peptone. The first was that of a widow over eighty years of age, of robust constitution, and sanguine temperament; she had hemiplegia on the right side, and partial aphasia following a cerebral effusion which dated more than thirty years back; all the functions were normal. In the spring of 1884 she had another cerebral attack, but the symptoms disappeared under the influence of internal and external derivatives. In 1885, she had a third attack, which lasted longer than the preceding one; paralysis became more pronounced, aphasia more complete, and deglutition more painful, without any local change in the throat. The patient refused all nourishment. When obliged to take food, either solid or liquid, she immediately vomited it. Pure water, sweetened or aërated, was immediately rejected. At the end of six months the patient was extremely feeble. Dr. Labastide then decided to administer peptone. Injections of twenty grammes of "peptone Dufresne," mixed with sixty grammes of boiled milk, were given, broth being occasionally substituted for milk. After twenty days of this regimen, the patient had rallied from her state of prostration; her stomach retained water, and even milk, when taken in small doses at long intervals. Twenty grammes of peptone, mixed with a little tapioca, were then ordered three times a day. After fifty days of this treatment, the patient, though still paralyzed, had recovered her former condition, and had even begun to grow stout. At the end of March, however, she succumbed to a fresh cerebral attack. The second case was that of an infant nine months old, of an extremely feeble constitution. At the cutting of the first tooth symptoms of inflammation of the intestines appeared, together with wasting. Aphthæ of the mouth prevented the child from taking the breast. Dr. Labastide then had recourse to injections of peptone, ten grammes of which were given with twenty grammes of milk, a drop or two of laudanum being occasionally added. The little patient was nourished in this way for two months, and gradually gained strength. At the end of that time it could take peptone, mixed with weak milk taken from its mother, or with tapioca. After five months' treatment, all trace of cachexia had disappeared. The third case was that of a child nine years old, of nervo-lymphatic temperament, and fairly good constitution. It had every symptom of anæmia, pallor, palpitations, headache, enlarged glands in the neck and elsewhere, and exostoses on both tibiæ. No treatment had been of any benefit. Peptone was then administered in doses of one, and, subsequently, two tablespoonfuls. In a few days the tumors on the legs began to disappear, the swelling of the glands diminished, the appetite returned, the little patient recovered his strength and color, and the limbs could be moved without effort. The child no longer suffers from headaches or palpitations, and is now completely cured.

Note on the Cause and Cure of a Form of Backache.

Sir James Sawyer thus writes in the *Lancet:*

Early in the year 1881, in a note which was published in a weekly professional journal, I asked the attention of my brethren to a form of backache which had not, so far as I know, been described before. I desire now to refer to this subject again, and to record that my further experience in practice has confirmed my previous remarks upon the point in question.

Subjective symptoms are always important diagnostic signs, and they are often clear therapeutic indications. Amongst such sensations backache is frequently a leading symptom, and also one which is pressingly dwelt upon by patients. Of backache there are divers forms. Dr. George Johnson, in an able clinical lecture, and Mr. William Squire, in a practical memorandum, have drawn the attention of the profession to many of these. But they have not mentioned a variety of backache in which the cause of the pain is traceable to the condition of the large bowel. I find that some patients complain of pain, aching, dull, and heavy in character, and extending "right across the back." When asked to point out its position, they indicate this by carrying a hand behind the trunk and drawing the extended thumb straight across the back, in a transverse line, about half way between the inferior angles of the scapulæ and the renal region. This pain I venture to attribute to a loaded colon; I conclude I have correctly found its proximate cause in fæcal accumulation in the large intestine. I have found it disappear after the exhibition of an efficient cathartic. This form of backache is a concomitant of habitual constipation, and is especially significant of the alvine sluggishness of sedentary persons. In such a condition, as I have stated elsewhere, I find aloes, given in combination with iron, to yield the

best results. We owe the valuable suggestion of combining iron with aloes, when aloes is given for laxative purposes, to the late Sir Robert Christison. He showed that the cathartic property of aloes is much increased by its combination with sulphate of iron. Dr. Neligan, Dr. Kent Spender, and Dr. David Bell have confirmed this experience. I prefer Socotrine aloes, and I give of it one, two, or three grains in a pill, combined with a quarter of a grain of sulphate of iron and one grain of extract of hyoscyamus. This pill should be taken every night. We must aim at producing a full alvine evacuation after breakfast. When a saline cathartic is indicated, I usually employ the old-fashioned Rochelle salt. This "goes" well with tea, coffee, or cocoa. One or two teaspoonfuls may be taken at breakfast, dissolved in a large cupful of one of these beverages.

A Case of Fracture through the Base of the Skull.

Dr. D. Jamison thus writes in the *Med. Press:*

I venture to give publicity to the following rough notes of a case of fracture through the base of the skull, as they may perhaps be of some interest as showing the long time during which the cerebro-spinal fluid sometimes continues to flow from the ear in cases where the fracture passes across the internal auditory canal, and is attended with rupture of the membrana tympani.

Some months ago I was called to see a boy who had been knocked down at a race course by a runaway horse. He alighted, I was told, on the side of his head, and was unconscious for some length of time.

A scientific agriculturist who was present suggested phlebotomy, and proceeded to operate by the somewhat unusual and unsanitary method of sucking the patient's nose. After having been aspirated in this infantile manner for some time, the patient became partially conscious, and vomited. He was then put upon a car and driven home, some six miles. It was then I saw him. He was conscious but confused. Pupils unequal; face flushed; pulse quick; vomiting frequently. Vomit contained good deal of blood. Blood was coming from one ear freely, and there was great pain in the head. Ice was applied to his shaven head, and the usual treatment pursued. For the next three days the blood continued to drain away by the ear, and the pain continued in the head. One side of the face was more expressionless than the other, but there was no loss of power over the obicularis palpebrarum muscle.

He was much troubled by a tickling cough, which was evidently caused by blood passing down the eustachian tube. It was relieved for a time by swallowing.

On the fifth day the blood ceased to come from the ear, but was replaced by a clear limpid fluid, which continued to ooze from the ear for the next nine days. During this time the patient was dull and stupid. He did not like to speak or to be spoken to. Was constipated and ate very little. Objected to light, and complained of loud noises in the head. On the ninth day from the first appearance of the clear discharge it stopped somewhat suddenly. From this on the patient improved rapidly. Two days after it stopped, he wanted to get up, and said he felt quite well, I had great difficulty in persuading him to remain a few days longer in bed. His hearing is dull on the injured side, but otherwise he is quite well.

The Cotton Compress in Orchitis.

In a recent number of the *Revista Argentina de Ciencias Médicas* Señor José M. Escalier gives an account of a very successful method of treating orchitis and epididymitis by means of a cotton compress, which has been for some time in use in Dr. Montes de Oca's wards in the Hospital de Clinicas in Buenos Ayres. The idea was taken from the cotton cap or suspensory bandage of Langlebert. The apparatus is applied as follows: The neck of the scrotum is first secured by a bandage and strapping, the testicles being thus driven downwards. The scrotum is then enveloped in a silk handkerchief, outside which a thick layer of cotton wool is applied, and the whole covered with a gutta-percha cap. Strips of plaster are now passed round in a circular manner, so that the ends can be drawn more or less tightly before being fixed, in order to exert a compressing force on the glands. In the first stage of orchitis, when there is not much epididymitis, the compress arrests the inflammation and brings about resolution rapidly. The cases in which this occurred, however, were but few, as nearly all the patients who presented themselves at the hospital had passed that stage. In some cases of acute orchitis very moderate compression was resorted to with success, but of course the pain was very great and the patients did not bear it well. In these cases the best treatment was found to consist in making a number of

punctures to give exit to the liquid in the tunica vaginalis, together with some blood, then to surround the scrotum with ice, and to give a purgative. After this treatment has reduced the inflammation, the cotton compress can be applied with advantage. With practice the degree of tension required in each case can be adjusted to a nicety, and in twenty-four hours the swelling will generally have diminished so much that it is necessary to reapply the compress. After two or three of these reapplications, the testes return to their normal size, and a slight induration of the epididymis is all that remains. The cure is usually complete in a week, or even less. The cotton compress has been used in more than a hundred cases, and is, according to the writer, far more satisfactory than any of the ordinary methods of treatment. Even in chronic cases it is astonishing to see the rapid effect that it produces. It has also been successfully employed after tapping hydroceles.

Absorption of Fat in Acute Intestinal Catarrh.

Dr. Viazhlinski, who has been working in Professor Ivanovski's laboratory of pathological anatomy in St. Petersburg, has published an interesting paper on the question of the absorption of fat in acute catarrh of the small intestine. The literature which he first alludes to comprises more than ninety papers, etc., including those published by Goodsir Schäfer, and Watney in this country. His own observations were conducted by inducing acute intestinal catarrh in animals by means of irritant drugs, and then feeding them with milk or other fat-containing food, after which the animal was killed and the intestinal villi examined with the help of osmic acid, which he found the most satisfactory agent for making the preparations. The drugs used were colchicin and croton oil. Several animals (cats and dogs) died, so the quantity of colchicin was reduced from one-thirtieth to one-sixtieth or one-hundredth of a grain, which produced choleraic stools. Croton oil was given in repeated doses of five or six drops, producing diarrhœa with exhaustion. When the animals presented, besides diarrhœa, an inflated abdomen, constant borborygmi, and a considerable degree of exhaustion, an acute catarrh of the small intestine was considered to have been established, and the fatty food was administered. The microscopic observations showed that in catarrhal conditions, as well as in health, the fatty particles are absorbed by their inclusion within round or amœboid cells—*i. e.*, leucocytes—the difference in the diseased state being merely a quantitative one. No evidence could be obtained of any part being taken by the epithelial cells in the absorption of fat.

A New Treatment of Gonorrhœa.

The *Boston Med. and Surg. Jour.* says that Castallan, of St. Mandrier Hospital, starting with the view, now popularly entertained, that gonorrhœal urethritis is a parasitic disease, and being led by observation to believe that the microbe can only live in an acid medium; finding, moreover, that in this disease the discharge is, as a rule, acid, proposes to treat gonorrhœa in the acute stages by urethral injections of sodic bicarbonate; three or four injections being made daily of a one per cent. solution. For this treatment, which is but a logical inference from the premises, he claims remarkable success, although the cases on which it has been tried in St. Mandrier, as yet, number only a dozen. The injections of bicarbonate of soda are commenced as soon as the discharge appears, or the patient comes under observation; the urethral secretion is tested every day with litmus paper, and the injection is kept up till the discharge becomes alkaline or neutral. For internal treatment the patient is given flax-seed tea, with occasional doses of bromide, if there seems to be any indication for the sedative effects of this salt. His conclusions are as follows:

1. The urethral pus in the first stages of the disease is generally, if not invariably, acid; this acidity is quite pronounced.

2. The treatment by bicarbonate of soda rapidly lessens the discharge; it also rapidly diminishes or removes the pain in micturition.

3. In old urethrites, and in those which have been treated by the usual injections, it speedily brings about a cure.

Reviews and Book Notices.

Notes on Current Literature.

——*Godey's Lady's Book and Magazine* appears fresh for the year with improved cuts, attractive stories, complete fashion plates and news, and all the other features requisite to make it a thoroughly popular home magazine. Address *Godey's Lady's Book*, Philadelphia, for circular, etc.

BOOK NOTICES.

A Manual of Operative Surgery. By Joseph D. Bryant, M. D., etc. Contains about 800 illustrations. Cloth; 8vo., pp. 530.

To the many treatises on surgery which have recently appeared we have here added another by the professor of that branch in the Bellevue Hospital Medical College, New York city. As we might expect, coming from his pen, it is an admirably arranged production, and the facts set forth in lucid and excellent English. The illustrations are numerous and of superior finish, while the manufacture of the book leaves nothing to be desired.

The author aims to cover the ground of ordinary surgery, not including, however, that of the eye and ear and that appertaining to diseases of women. The operations he illustrates are those most approved by modern experience, and he gives ample information about after-treatment, bringing into strong light the value of the antiseptic plan.

A careful index completes the volume, and we are glad to commend the whole as a work of the highest utility.

A Text-Book of Medicine. By Dr. Adolf Strümpel. Translated by H. F. Vickery, M. D., and P. C. Knapp, M. D., with Notes by F. C. Shattuck, M. D. 8vo. cloth. Pp. 981. New York. D. Appleton & Co., 1887.

Dr. Strümpel, who has for some time been connected with the University of Leipsic, has endeavored in this volume to present an account especially of the current clinical knowledge of internal diseases. In Germany his production achieved prompt success, and three editions have been called for in as many years. Certainly his volume is much more practical, much more useful to the physician as a practitioner, than most of the German treatises on medicine. It, nevertheless, indicates the general tendency of German teaching to overlook the value of treatment as compared with pathology—a view which is acknowledged, and we regret to add condoned, by the editor, Dr. Shattuck, in his preface.

His descriptions of diseases are vivid, and evidently drawn from close personal study. He is strongest in the domain of diseases of the nervous system, where the general practitioner particularly needs a firm guiding hand. But we have also been well satisfied in reading what he says of cardic diseases, and consider that he deserves commendation throughout for terseness and clearness.

The translation appears to be accurate, and is at any rate good English, which is saying a great deal for most translations from the German. No doubt the work in its present shape will have a favorable welcome in the United States.

The Science and Art of Obstetrics. By Theophilus Parvin, M. D., LL. D., etc. Illustrated; 8vo.; sheep; pp. 701. Philadelphia, Lea Brothers & Co., 1886.

This treatise, by the professor of the branch in the Jefferson Medical College, has been the result of years of careful study directed to the presentation of the subject in the most complete manner consistent with the limits of a manual of instruction. Dr. Parvin's well-known literary ability gives him unusual advantages for precisely such an undertaking; and he is to be congratulated on the success with which he has accomplished it.

The plan of the work is as follows: After a brief introduction, he describes the anatomy and physiology of the female sexual organs, and the characteristics of puberty, ovulation and menstruation. Two hundred and twenty-five pages are next devoted to pregnancy, its physiology and symptoms, its pathology and medical management, and the life and maladies of the fœtus in utero. Labor proper comes in for about an equal share of attention, during which its normal and anomalous progress is discussed, and its various complications set forth. The puerperal state is treated separately, first as regards its physiology and management, and then the treatment of its pathological phases. The volume closes with a series of chapters on obstetric operations, where the various instruments are depicted and their use described.

It will be conceded that this is a perspicuous disposition of the theme, and its details are brought out with no less literary skill than scientific precision.

An Epitome of the Newer Materia Medica, Standard Medicinal Products, and Fine Pharmaceutical Specialties, introduced and manufactured by Parke, Davis & Co., to which is added a complete property and dose list of all the fluid, solid and powdered extracts, German tinctures, normal liquids and concentrations, prepared by them. 8vo., pp. 76; fourth edition. Parke, Davis & Co., Detroit, Mich.

The purpose and scope of the above work are so fully set forth in the title-page that we have only to add that a paper-bound copy will be mailed, without charge, to any physician applying for the same.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE PUBLICATION OF EXTENSIVE MEDICAL WORKS.

While in most business enterprises our merchant is far ahead of his European brother, in some branches we can learn from our confréres on the other side of the Atlantic. To a great extent the latter remark is true in its application to the trade with medical books.

It was on the continent of Europe that they first conceived and executed the idea of combining a large number of more or less eminent medical men in the publication of some extensive medical work. Thus the various cyclopædias had their origin, and undoubtedly also their usefulness. Medical sciences have progressed so rapidly during the last thirty years that about ten or fifteen years ago there was a general desire amongst all physicians to have some comprehensive work, written by eminent authors, that could give them a general understanding of all the immense progress made all over the vast field of medicine.

Ziemssen's work and similar great cyclopædias in Europe thus arose and answered their purpose. We also published here a similar work, which found its justification in the well-recognized fact that medical practice in our country differs in more than one important detail from that of our cousins and more remote relations across the ocean. There being a necessity for it, naturally a market offered, and all the works mentioned had a well merited success.

But we are glad to find in an editorial of the *Allg. Med. Zeitsch.*, one of the oldest and best informed medical journals on the continent of Europe, a remark which proves to us that an idea we had conceived long since is being recognized as the true one all over Europe. "The time for cyclopædias and other extensive works and journals, archives, etc., has gone by, and another period has arrived, in which the demand is mainly for not extensive monographs on special subjects by writers eminently fit to speak on on their subject, and a period in which the medical journal again assumes its accustomed place."

These words indicate plainly the spirit of the times. Perhaps for the next twenty or thirty years we do not need any cyclopædias or extensive archives: what we want to know are the thorough investigations and the results of the ripe experience of the specialists. These are demanded by the general physician, and not in the form of exhaustive works containing a great deal already known, but in the shape of smaller volumes, which

simply speak of their subject, and not of everything that had any connection with the same during the last 2,000 years. Meanwhile the medical journal again receives the accustomed supply of the real news all over the world, and *it* more than authors can do, instructs the general physician and specialist in what their confréres all over the world have done.

Years hence, the meanwhile greatly accumulated material may have to be sifted once more, and the necessity may once more arise for cyclopædias; but publishers, who value their pocket-books, should no longer engage in such enterprises, but try to bring into the market the experience of the few instead of publishing the half-knowledge of many. Everything can be overdone, and whoever adopts last an idea already forsaken by others as antiquated, will have to blame only himself for the loss sustained.

Probably one other reason for the demand of smaller works on special subjects is the fact, that the field of medicine has become so great, that most care only to be experts in what they thoroughly understand. They either do not desire to read anything else, or they prefer to have everything not connected with their specialty in such a concise form, that they can readily get at it when needed. Every general practitioner is more experienced in some branches than in others; he studies mainly his favorite ones, but when he has occasion to treat a case with which he may not be so thoroughly acquainted, he must be able to obtain the knowledge he looks for, without being forced to digest a lot of material foreign to his taste. Publishers will do well to make a note of these facts.

LEAD IN PRESERVED FRUIT AND VEGETABLES.

We generally assume that there is no danger in canned goods, as they are kept in vessels made only of tin, which, as its ingredients are not soluble in the canned material, is generally considered an innocuous material. If nothing else were present, it would be all right, but most persons forget the lead which forms one of the ingredients of the metal used for soldering the can. This solder always contains more or less lead, and as the investigations of Dr. Rjaeltschevski, in Petersburg (Russ., Dec. 10, 1886, *Wratch*), have proved, this percentage varies from 59 to 69! Lead is one of the most soluble substances known—water, to which the least amount of organic substance has been added, even dissolving it. But the moment the fluid coming in contact with the solder contains the least percentage of organic—vegetable or animal—matter (and all canned goods consist of such), the lead in the solder is at once dissolved, at least partly, and the degree of colicky pains, if nothing worse results, will testify to the percentage of lead dissolved.

There is no doubt that obscure abdominal pains, gastric and intestinal troubles, and similar digestive disturbances, have become more frequent since the introduction of canned goods than they formerly used to be. Some method should be invented by which the solder is either prevented from coming in contact with the contents of the can, or the latter should be sealed with some substance not containing lead.

Notes and Comments.

Tannin in Tuberculosis.

At a recent meeting of the Biological Society of Paris, M. Arthaud made a communication respecting his researches, in conjunction with M. Raymond, on the etiology and treatment of tubercular affections. Three substances had given satisfactory results: (1) Sulphide of carbon, (2) iodoform, (3) tannin. Experiments were made on rabbits, which were submitted to the action of these substances and examined at the end of a month, in order to ascertain whether they could be inoculated with tubercle. No very decided result followed the use of iodoform, or sulphide of carbon, probably owing to the method employed for introducing those substances into the organism; with tannin, however, the results were very remarkable. Six rabbits were treated for a month with doses of tannin, varying from 50 centigrammes to 1 gramme; after two successive inoculations, one, with lung-tissue from a patient who had died of acute tuberculosis; the other with miliary tubercle from a hospital patient, no trace of infection was observed, whilst three other rabbits, to which tannin had not been given, succumbed in consequence of inoculations with the same material. These experiments suggested a mode of treatment which has been adopted with excellent results in over fifty cases. Tannin was given in doses of from two to four grammes a day, and the improvement was visible at the end of a fortnight, the patients had increased in weight, and no relapse occurred. In cases of acute tuberculosis, both in children and

adults, it sometimes happens that the symptoms appear less favorable; but, at the end of a week or a fortnight, the patient's condition improves, even when fatal results have been feared. From these experiments the following conclusions may be drawn: (1) That tannin is preferable to sulphide of carbon or iodoform in the treatment of tuberculosis; (2) that animals submitted to this treatment for a month offer great resistance to the action of tubercular virus.

Erysipelas of the Upper Air Passages.

Dr. Wm. Porter calls attention to this subject, which he is convinced is an important one, in the *New England Med. Monthly:*

As found in erysipelas elsewhere, the migratory tendency of the disease in the air passages is worthy of note. Sometimes beginning externally, it extends from the nose, mouth, or ears, along the mucous tracts into the pharynx; or beginning in the pharynx, it may wander into the larynx, or from the larynx there may be extension into the lungs. This tendency and the constitutional symptoms which resemble those of erysipelas, serve to distinguish it from ordinary acute pharyngitis and laryngitis.

In the treatment of erysipelas of the upper air passages, and especially of the larynx, in addition to what is indicated in the disease as occurring elsewhere, we must be on our guard against a fatal result from dyspnœa. Insufflations of morphia and starch, with free use of ice, and bromide of potassium internally is commended by Dr. MacKenzie. Dr. Love, of St. Louis, strongly favors the internal use of pilocarpine in erysipelas, on account of its stimulating the functions of elimination, and this is endorsed by Cohen. Rohé has used mild alkaline sprays with a little alcohol with good effect. From the effects of cocaine in reducing and quieting the swollen mucous membrane under other circumstances, he believes it would be efficacious in this condition.

The general treatment of erysipelas need not be commented upon here.

Operative interference may be demanded, scarification first, and all else failing, tracheotomy, if only for present relief. The new procedure, intubation, is even better indicated than tracheotomy, in that it leaves no open wound.

Toxic Effects after Sulphate of Duboisin.

Before an English medical society, Dr. Chadwick described a case where one-hundredth of a grain of duboisin was used for examination of the lens in a case of senile cataract. The patient was aged 75, and it was suggested that advancing years gradually increased the susceptibility, until it reached its climax in extreme age. The similarity to the symptoms included under the vague term "softening of the brain," suggested the thought whether marked susceptibility in age betrayed a pathological condition of brain-substance liable to result in symptoms of cerebral degeneration and atrophy. The drug would appear to be indicated in cases of morphine poisoning; its use in ophthalmic practice could scarcely be upheld. The similarity between these toxic effects and the condition seen in cases of acute alcoholism and the post epileptic state did not appear to extend to acts of violence.

Dr. Major said the symptoms closely resembled those he had witnessed in a medical friend who for experimental purposes took a large dose of hyoscyamin, being characterized by strange antics and curious unreasonableness. He attributed much of the effect to delusions of vision.

Mr. Hartley had seen toxic effects resembling atropinism in four cases, but the drug was still used by Mr. Teale and himself, though in very weak solution. In one case he had seen great pallor, with sickness and vertigo, and unsettled mental condition.

Dr. Heller referred to Dr. Wood's experience of Indian hemp, as resembling in some sort the cases narrated.

Mr. Jessop had noted a case where delusions of vision in a blind woman were removed by a single dose of hyoscyamin.

Dr. Griffith said hyoscyamin had proved useful in surgical cases in the Leeds Infirmary, when there was delirium with insomnia after operations.

Mr. G. Carter related a case where a nightly dose of hyoscyamin given in a case of acute mania produced temporary blindness.

The Immediate Cause of Death in Malignant Cases of Fever.

Dr. C. H. Willey, in reading this paper, before an English medical society, said that the cases under consideration were those of scarlet fever and small-pox in which unconsciousness and death ensued at an extremely early stage. The pathology of this condition had not been explained. The conclusions to which Dr. Willey had arrived were based on clinical observations and post-mortem examinations in twenty-five of these malignant cases. The chief factors in the

investigation appeared to him to be that the fatal symptoms were, in each case, those of a rapidly failing circulation, and that, after death, the heart-chambers, especially the right, were completely filled with white, jelly-like clot, which was, he said, clearly of ante-mortem formation. The failure of the circulation (particularly in small-pox cases) ensues with great suddenness, and the question arose, Was this failure or the thrombosis the primary condition? Evidence from the main symptoms, and from such invariably accompanying ones as pulmonary œdema and copious diarrhœa, Dr. Willey said, goes to show that a failure of the circulation is the primary cause of death, and, further, that not only is the heart paralyzed, but the entire arterial system—in fact, a total collapse of blood-pressure throughout the vascular system is brought about with more or less suddenness by a functional failure of the sympathetic nervous system, governing, as it does, the cardio-motor and vaso-motor functions. The pulmonary œdema and the profuse intestinal flux are due to the same cause; they are undoubtedly associated with a greatly diminished blood-tension in the arterial system.

Reported Cure for Leprosy.

Under this heading, the *St. James's Gazette*, of December 17, quotes a portion of a letter from Father Damian, of the Molokai Leper Settlement, to a German publication, in which he shortly refers to and extols the wonderful effects of a treatment carried out at the Kakaako Leper Hospital by Dr. M. Goto, of Japan, who was invited over by the king. The treatment referred to is similar to that long carried out by Dr. S. Goto, of the Kihai Hospital, Tokio, Japan. It is hygienic, dietetic, and medical. Strong patients are bathed thrice daily, and weaker ones twice daily, in warm fresh water at 90° to 100° F., into which has been placed an infusion of a few ounces of Hichiyou bark (Æsculus turbinata), together with certain proportions of Taifuushi, sulphur, and other ingredients. The patients are fed generously, but not excessively, thrice daily, on rice, milk, beef, mutton, chicken, eggs, good strong broth, boiled taro, vegetables, and fruit; but sour poi and also raw fish, when used with the usual native condiments, are forbidden. The medical treatment "varies according to the condition of the patient and the stage and character of the disease." The two chief medicines used are, in all cases, Seiketsu-ren as pills and in large doses (? the bark of the Hoang-nan tree with realgar and alum), and yoku-yaku for baths. Dr. Goto also employs tincture of the perchloride of iron, sulphate of quinine, iodide of potassium, vegetable tonics and bitters, and the carbonate of soda and potassium, especially the alkaline salts. Under this treatment he reports, under date of April 20, 1886, five cases as "almost cured," nineteen as "improving," and seventeen as "relieved."

Syphiloma of Heart.

Before the Pathological Society of London, Dr. Pasteur read a paper on a case of diffuse syphiloma of the heart. The dead body of a woman, aged about thirty, was brought to the Middlesex Hospital. At the necropsy the heart was the only organ obviously diseased. The wall of the left ventricle and the septum ventriculorum were thickly studded with opaque, yellowish-grey patches of varying size. The endocardium was implicated in several places. There was a similar, but less extensive, affection of the right ventricle. Altogether at least one-half of the left ventricle and of the septum were diseased. Microscopical examination showed the morbid process to consist in an actively infiltrating corpuscular growth, very vascular near its spreading margin. Some of the vessels showed well-marked periarteritis. The central portions of the disease showed an early degree of degenerative change. There were no signs of fibrillation or fibrosis. The invaded muscular tissue underwent gradual atrophy without exhibiting degenerative changes. The liver was slightly enlarged, and its capsule normal. Sections showed areas of diffuse interstitial cirrhosis in a very early stage, in addition to slight general fatty change. Dr. Pasteur argued in favor of a syphilitic origin on account of the similarity of the change in the two organs, the anatomical characters of the new formation, and the fact that both the ventricles were affected.

Preventive Medicine.

Dr. C. R. Illingworth thus writes in the *Med. Press:*

One of our great aims as physicians is to prevent disease; another is to cut short its course whon developed. Our power in these directions finds full scope amongst that class of disorders now generally recognized as depending upon the reception, growth, and development in the tissues, of micro-organic life in one shape or another. By the continual suppression of the growth and devel-

opment of these forms of cell-life, we may, indeed, hope at length to erase the names of the diseases they cause from the category of those "ills that flesh is heir to." The diseases I refer to are scarlet fever, diphtheria, measles, whooping-cough, rheumatic fever, chicken-pox, small-pox, syphilis, hydrophobia, yellow fever, *et hoc genus omne.*

The germicide remedy I have found to answer as a specific and prophylactic in such diseases is the biniodide of mercury given in solution of potassic iodide. In all cases of scarlatina or measles occurring in one member of a family, I put the rest upon preventive medicine. Thus, for children I prescribe as follows: Bichloride of mercury solution, ℥iss; iodide of potassium, ʒj; ammoniocitrate of iron, ʒj; syrup, ℥iss; water to eight ounces. One or two teaspoonfuls to be given three times a day.

Fœtal Abnormality.

Before the Midland (England) Medical Society Mr. A. F. Hawkins showed an eight months' fœtus which presented the following abnormalities: The umbilical cord was 2½ inches long; there was ectopia abdominalis, the lining of the bladder being covered by a mass of meconium. The intestines opened into the left upper corner of the bladder, there being no distinction between the large and small gut; the penis was undeveloped, imperfect, and above the pubic arch, the latter being incomplete, and the two halves joined by a ligamentous band. The scrotum was divided, the right testicle lying loose in the abdominal cavity, with a stalk about an inch long; the left testicle was in front of the left kidney under the peritoneum. At the back a large cyst extended from the angles of the scapulæ above to the buttocks below; it was in the median line, about the size of a tennis-ball, and was lined by a smooth vascular membrane. It contained a perfectly clear, limpid fluid; no nerves were stretched across it. In the anterior portion were two depressions, one the size of a crow-quill, ¼ inch in depth and apparently blind; the other, which was higher, was an opening with circular and well-defined edges ⅛ of an inch in diameter; a probe could be passed through this upwards into the vertebral column. Both feet were clubbed; the hands normal.

Points in the Treatment of Gonorrhœa.

It will be well to paste the following recommendations of Dr. Otis in your hat, that you may have them always handy for reference:

1. Fully explain to the patient the inefficiency of popular remedies, and the dangers attending their use.

2. Secure absolute personal cleanliness, thereby preventing infection of other parts, and insist upon as nearly perfect rest in bed as the exigencies of the case will permit.

3. Soak the penis frequently in water as hot as can be borne, but more especially during the act of micturition.

4. Recommend milk as a diet, and prescribe alkaline diuretics and mineral waters as internal medication.

5. Secure absolute freedom from sexual intercourse and from thoughts associated therewith.

Perfect faith in, and obedience to, these simple formulæ he insists will insure a successful ending of all uncomplicated cases before the beginning of the seventh week.

The Treatment of Pleurisy with Effusion by Hay's Method.

Professor William Osler, in a clinical lecture, reported in the *Medical News*, calls especial attention to the treatment of pleural effusions, as well as general dropsies—renal or cardiac—according to the method of Professor Matthew Hay, of Aberdeen.

The method consists in giving a concentrated solution of a saline cathartic, at a time when there is very little fluid in the intestines, thus causing a rapid concentration of the blood, owing to the abstraction of water to form the intestinal secretion excited by the salt. Professor Osler orders the patient to take nothing after the evening meal, and then, an hour before breakfast, administers 4 to 6 drams of magnesium sulphate, in 1 ounce of water. The patient must not drink after it. This will usually produce from four to eight watery stools, without pain or discomfort. Attention is also called to another point, namely, that the salt also acts as a diuretic.

An Artificial Ramus and Condyle.

Dr. Cunningham, at a recent meeting of the Odontological Society of Great Britain, showed a very ingenious apparatus, invented by Herr Rosenthal, which was designed to meet the following difficulty: The ramus and condyle of the lower jaw having been removed for a sarcoma, it was subsequently found that the other side became dislocated, and, after reduction, for which an anæsthetic

was required, slipped out again immediately. Gold bands were fitted accurately to the last molar of each jaw on the side where the bone had been removed, to the upper of which a thick slightly curved wire was soldered. This wire fitted loosely into a tube soldered to the band round the lower tooth, and the bands themselves were fixed to the teeth by screws tapped into them. The apparatus entirely prevents the dislocation, and although there is no lateral movement the patient can eat fairly well.

The Use of Cocaine in Coryza.

Dr. Amory Chapin writes to the *Medical Record:*

"I desire to attest the beneficial results of cocaine in acute coryza. I have used the cocaine solution on a number of patients with throat and nose disease who have been and are subject to 'cold in the head,' and have prescribed for their own use the four per cent. solution of cocaine whenever they were troubled with the disagreeable affliction, and it has been almost universally successful, often aborting the disease. I have found the combination of 'Dobell's Solution' with the cocaine work better even than the cocaine alone. I advise the use of the combination solution in an atomizer (hand bulb), and recommend that the solution be warmed to an agreeable temperature before being used in spraying the nares."

Epithelioma of the Lip Removed by the Aid of Cocaine.

A man came to Mr. Johnstone Harris (*Lancet*, January 1,) with a growth on his lower lip. It had been there for some time, but within the last month had rapidly increased in size. On examination he found it to be an epithelioma, and decided to remove it. The man objected to the administration of chloroform; so he injected on either side of the growth a four per cent. solution of cocaine, and dusted the mucous membrane of the lip with hydrochlorate. After waiting ten minutes he removed the growth, and such was the good effect of the cocaine that he was enabled to take time and perform the operation with great exactness. The man expressed himself as feeling no pain, and the after progress was excellent.

Agaric in the Sweating of Phthisis.

Dr. A. Peter writes to the *Medical News* that he has used it in five cases with the greatest success. In the first place he prescribed the powder in ten-grain doses at bedtime. Owing to its cathartic effect, he reduced the dose to five grains. Continuing this for a week, all sweating ceased. He now, in this case, only uses it when a slight moisture of the skin during the night warns the patient that he may be going to have a return of the sweat. In one case he had to repeat a five-grain dose every two hours, three times one night; no cathartic effect resulted. He calls attention to this remedy because when he first ordered it he found great difficulty in obtaining the smallest quantity, either of the powder, the alkaloid, or the fluid extract. The remedy, while so effectual in controlling the sweating, did not help the cough or produce drowsiness.

Treatment of Urethral Caruncle.

Dr. Percy Boulton recommends an inquirer in the *Brit. Med. Jour.* to paint the urethral caruncle and urethra surrounding it with a ten per cent. solution of cocaine. In five minutes he can snip off the caruncle with a pair of slightly curved scissors. If he holds the caruncle with anything to draw it forward, he should use dressing forceps rather broader than usual at the points, as these growths tear easily and bleed profusely. The bleeding can be stopped at once by the application of Paquelin's cautery, and, in many cases, pressure of the urethra against the pubes by means of a plug of wool in the vaginal orifice is quite sufficient. The operation, performed in this way, is exceedingly simple, effectual, and painless.

Toothache Drops.

The American *Journal of Pharmacy* gives the following:

Dissolve mastic 8 parts in chloroform 14 parts, and add balsam of Peru 5 parts. A few drops upon a little cotton are to be introduced into the cavity of the tooth.

Liquefy camphor and chloral hydrate, of each 5 parts, and add cocaine 1 part. A pellet of cotton soaked in this liquid and introduced into the cavity of the aching tooth is said to afford complete and lasting relief.

Elephantiasis.

Before an English medical society, Mr. Atkin showed a case of elephantiasis arabum. The patient, a woman, aged thirty-three, was a native of Perth, and had the disease as long as she can remember. It

was localized to the right leg, and there was no history of syphilis, malaria, chyluria, or swollen glands. Attention was drawn to the fact that the most successful treatment of the disease could not be explained by the generally-accepted view of its pathology. The only remedy from which the woman had derived comfort was iodoform in the form of ointment. Powders and lotions caused great irritation. In case the leg got worse, Mr. Atkin proposed to tie the external iliac.

Oil of Gaultheria in Rheumatism.

Dr. D. H. Luke has excellent results from its use, which he reports in the *College and Clinical Record*. The dose should be from ten to twenty minims every two or three hours, according to tolerance. He failed to notice in any of the cases under his observation the depressing effects so often produced by large doses of salicylic acid. It is true the oil caused some nausea and gastro-intestinal irritation, but these only after the more important symptoms of the disease had subsided.

Chloride of Gold and Sodium.

It may be well to know that when the chloride of gold and sodium cannot be obtained from the usual sources, it may be procured from photographers, who use it in finishing processes for certain portions of their work. Prof. Bartholow continues to advocate and claim for this remedy the efficacy of its use in the various scleroses. Especially is he most positive in his assertions as to its benefit in interstitial nephritis after the acute symptoms have subsided.

Fomentation Bag.

Before the Glasgow Obstetrical Society, Dr. Sloan exhibited an India-rubber bag with an afferent and efferent tube, whereby uterine and vaginal fomentation might be maintained during pleasure. He said the invention was due to Alexander Robertson, one of the physicians to the Royal Infirmary. Water from 110° to 115° could be used, and for as long as half an hour at a time. The effect was found to be very grateful in inflamed conditions.

Scriveners' Palsy.

A case of scriveners' palsy, says the *College and Clinical Record*, was recently treated by Prof. Da Costa in the following manner:

Put the hand at rest by splint, and every second or third day use alternate douches of hot and cold water. Begin the injection of one-eightieth grain of strychnine every second day, and gradually increase to one-fiftieth, into the affected parts.

Chorea.

The *College and Clinical Record* tells us that Prof. Da Costa continues to derive good results by the administration of hyoscyamine in cases of chorea which have resisted other treatment. In a recent case, a child aged five years, it was given in $\frac{1}{300}$ grain doses, ter die, to be increased.

Correspondence.

Felons.

Eds. Med. and Surg. Reporter:

I noticed in the Reporter some time ago a remedy for felons, recommended by Dr. W. H. Halbert, which, though possibly effective, is too complicated, and takes too long. It consists of salt and oil of turpentine, and must be continued several days to effect a cure. If Dr. H., or any one else, should have a felon to treat, I would advise him—somewhat after the style of the old English recipe for cooking a hare, "First catch your hare"—first diagnose your felon, then apply a fly-blister the size of a nickel, allow it to remain twenty-four hours, and that will end your felon.

You need no isinglass plaster or surgeon's silk, or wrapping of any kind except a rag or something to keep to keep the blister to its place. The fluid remaining after the blister is removed will soon be absorbed, the pain will be gone, and the felon, or the finger rather, will soon be well.

In this connection I will state that the most effective remedy I ever used for corns, bunions, etc., is a mixture of equal parts of tincture of iodine and castor oil. Moisten the corn or bunion with it two or three times a day, and if it does not cure, it will give relief for a long time, until ill-fitting shoes bring on trouble again.

Wm. F. Mitchell, M. D.

Addison, Pa., Jan. 10, 1887.

Rubber Goods.

Eds. Med. and Surg. Reporter:

In the Reporter of November 25, 1886, I was pleased with the information of Mr. Bailey and Dr. Chenery, although it is not

very gratifying to learn that we have no American manufacturers of rubber goods who make a reliable article for those who need it most.

On two occasions I have been obliged to resort to my Field tourniquet, as both the bandage and tourniquet of Esmarch broke in several pieces when I attempted to use them. Such accidents are embarrassing to the surgeon, and there ought to be a means of remedying the defective rubber goods, or the making of a better and more reliable article. Why can we not have a manufacturer of rubber goods for the medical profession with a reputation like Tiemann for instruments or like Squibb for medicines? We are willing to *pay for* a reliable article. Why do the manufacturers give us a poor one?

W. N. Sherman, M. D.

Holbrook, Arizona.

News and Miscellany.

How He Got Rid of His Room-mate.

An exchange tells the following good story:

A Frenchman had been assigned to a very comfortable room, and was about to disrobe, when there came a knock at the door. Upon opening it the announcement was made by an attendant that, owing to an unusual arrival of guests, etc., the proprietor would be obliged to put another gentleman into the room, and a cockney Englishman appeared. The Frenchman was disgusted, of course, and at once set his wits at work to devise means to oust the intruder upon his comfort. Pretty soon the Englishman touched the call-button, and, when the summons was answered, said:

"Portah, bring me a pair of large, clean towels."

The door had hardly closed, when the Frenchman touched the button, and upon the boy's appearance said:

"Garcon, bring me two pair large, clean towel."

The other frowned, performed his ablutions, followed by the Frenchman, when he again touched the button.

"Portah, send me up a bottle of Bass ale."

The Frenchman followed suit at once, demanding "two bottel Bass ale." The Englishman was now annoyed, but he held his peace, and, a little later, made another call upon the porter, which was immediately double-duplicated by the Frenchman. Then he began to lose his temper, and after a fourth demand and another—to him—insult from the Frenchman, he struck the button so violently that the porter appeared again in hot haste.

"Boy," said he, angrily, "go to the proprietor at once, and tell him I must have a bed in a room by myself, where I can rest in peace."

The boy had hardly reached the stairs when the Frenchman called him back, and, gesticulating wildly, made known his wants as follows:

"Garcon, garcon, vill you tell ze proprietaire to come here ver quick? By gar, I moost hav two bed in two room, vere I can rest myself in two pieces."

That settled the Englishman, and his tormentor had the room to himself without further trouble.

Goitre and Cretinism in Peru.

An interesting paper on Goitre and Cretinism in Peru was recently read to the "Union Fernandina," a Lima medical society, by Señor Antonio Loreña, who seems well acquainted with the European literature of the subject and the various theories which have been proposed to account for the endemic origin of these affections. He himself believes that no one of the suggested causes is alone sufficient to induce them, but that a most important factor in their etiology is a purely vegetable diet. He gives a detailed description of the valley of the Vilcamayo, in part of which goitre and cretinism are abundant, while in other parts they are absent, or nearly so, the general conditions remaining the same, with the exception of greater civilization and admixture of animal diet in the localities where goitre is absent. In some places, where forty years ago goitre was common enough, it has now nearly disappeared, the more intelligent inhabitants themselves attributing the change to the improved diet of the people. The author thinks the best prophylactic measures consist in opening up the valleys where goitre and cretinism is rife by means of roads, and stimulating the commerce of the district, which will lead to the peasants obtaining a more varied and palatable diet than the maize, which is now their sole article of food. Humboldt was, according to Señor Loreña, misinformed when he was told that goitre was unknown in South America before the eighteenth century, for there are preserved in many private museums wax figures with immense goitres dating from the times of the Incas, and there is now no doubt that goitre

and cretinism existed during the empires of the Incas and Siris just as they do at the present time.

Thirty-eighth Annual Meeting, American Medical Association.

Section of Obstetrics and Diseases of Women.

The following papers are announced for the June meeting in Chicago:

J. E. Kelly, New York, "Lithiasis in Pregnancy."

Charles Meigs Wilson, Philadelphia, "The Technique of Ovariotomy."

Hiram Corson, Plymouth Meeting, Pa., "The Treatment of Abortion."

Wm. T. Taylor, Philadelphia, "Eclampsia."

W. S. Caldwell, Freeport, Ill., "Intrauterine Therapeutics."

Geo. F. French, Minneapolis, Minn., "The Chief Source of Danger from the Use of the Uterine Sound."

B. E. Hadra, Austin, Texas, "Hysteria and the Ovaries."

The following gentlemen have signified their intention of contributing papers, but have not yet announced the topics: W. M. McPheeters, St. Louis, Mo.; A. McLaren, St. Paul, Minn.; John M. Keating, Philadelphia, Pa.; W. H. Wathen, Louisville, Ky.; W. H. H. Githens, Philadelphia, Pa.; Howard A. Kelly, Philadelphia, Pa.; W. P. Manton, Detroit, Mich.; A. H. Halberstadt, Pottsville, Pa.

F. M. Johnson, M. D., *Ch'n.*
Kansas City, Mo.
W. W. Jaggard, M. D., *Sec'y.*,

Antimony Poisoning During Pregnancy.

A case of attempted poisoning by antimony has recently occupied the courts in New Zealand. The criminal was a man named Hall, of good position; he was married last year, and shortly afterwards he insured his wife's life for a sum of money sufficiently large to free him from all difficulties. The time he selected to give Mrs. Hall poison was when she gave birth to a child, and he seemed to have had little fear of detection. He openly bought books on poisons from booksellers in Tamaru, and quantities of antimony and colchicum from the druggists. Dr. McIntyre, who attended Mrs. Hall during her confinement, was at first puzzled by her symptoms, but very soon came to the conclusion that she was being poisoned. He consulted with other medical men, and the result was that he laid an information which led to Hall's arrest, evidently just in time to save the wife's life. With Hall was arrested a Miss Houston, who lived with the family as lady-companion or lady-help. Hall was found guilty, and was sentenced to penal servitude for life. Miss Houston was acquitted, and declared by the jury, in the customary phrase, "to leave the court without a stain on her character." Dr. McIntyre, who laid the information, has won universal praise for the courage and promptness with which he undertook a terrible responsibility, and prevented the completion of a hideous crime. Some months before the arrest of Hall, his father-inlaw, Captain Cain, died; but no suspicion was excited at the time. Later events, however, led to the exhumation of the body, which was found to contain antimony in large quantities.

If the Dog Howls the Patient Must Die.

In one of our neighboring cities, one of the physicians was called out into the country to see a sick girl. He prescribed, and the medicine was gotten, but the patient got worse, and in a few days died. The doctor now found out that they had not given her the medicine; that which he prescribed on Tuesday was given on the following Sunday. When he asked the reason why his directions had not been followed and the medicines given, the farmer said: "Doctor, I thought it would be of no use to give her the medicine; our dog howled so nights that I knew she would die."

The man was ignorant enough to believe in the old superstition, that if somebody is sick and the dog howls near the house, nights, the patient wlll surely die. His belief in this was so strong that he would not give her any more medicine, but he called in one of those so-called faith-cure women, who was allowed to exercise her mystic influence and passes over the sick girl in preference to the physician's medicine.

A reader of the *National Druggist*, who sends the above to that journal, vouches for the truth of the same.

The Suicide of Professor Kolomnine.

The *Semaine Médicale* gives some particulars of the accident which led to the suicide of Professor Kolomnine. The professor had decided to perform an operation for the removal of tubercle from the rectum of a female patient, and inquired of his colleague, M. Louschinsky, what dose of cocaine he might administer. The answer was that the

maximum was two grains. Upon consulting special treatises, however, M. Kolomnine found that thirty cases of anæsthesia were recorded in which the quantity given had varied between six and ninety-six grains. In a similar operation to that he proposed to perform, a French surgeon had given forty-eight grains. In consequence of these references it was decided to employ twenty-four grains, which were introduced into the rectum by instalments. About half an hour after the operation the first symptoms of poisoning appeared, and notwithstanding the administration of nitrite of amyl, hypodermatic injections of ether, oxygen and artificial respiration, etc., the patient succumbed.

Chinese Treatment of Cholera.

The Chinese have a rather radical cure for cholera. A Shanghai paper says that on July 22 a Chinaman employed on one of the steamers was taken ill, apparently with cholera. The following is the course which was adopted, according to the paper from which we quote: "His friends immediately sent for a native doctor. This individual had with him a box containing some long needles, and these he used on the patient. A needle was driven some distance into the man's head, near each temple, and again behind his ears. In each case bleeding followed. Needles were also driven into the lips, both sides of the chest, both sides of the stomach, and also into the pit of it. The doctor then scraped the skin of the man's throat till it looked like the neck of a turkey. This violent treatment had the desired effect, and in a few hours afterward the man was quite well, and eating his midday meal with evident relish."

Apothecaries and Prohibition.

In consequence of extreme measures adopted by a prominent citizen of Quincy, Mass., says the *N. Y. Med. Jour.*, several of the apothecaries of the place have decided not to sell spirituous liquors even when ordered in the form of a prescription by physicians. They will, it is said, remove all liquors from their shops, on the ground that they cannot sell what they have not in stock. A leading physician of the town characterizes this action on the part of the apothecaries as "wholly unnecessary," and maintains that, inasmuch as physicians are frequently obliged to order liquor for their patients, the apothecaries can sell it under those circumstances without fear of molestation or prosecution.

Adulteration in Paris.

In spite of the keen watchfulness of the authorities, adulteration is still extensively practiced in Paris. Out of 645 samples of wines examined in November last, 450 were declared injurious; out of 88 samples of beer, 5 were bad; and of 18 samples of spirits only one was condemned. More than half the samples of water were reported to be dangerous, and 80 out of 370 specimens of milk were placed in the same category. Out of 81 loaves of bread 30 were worthless, and out of 22 specimens of wall paper only 5 were good. Coffee was very little adulterated, and the butter was also reported to be fairly satisfactory.

Phonographic Jubilee.

An International Short-hand Congress is to be held in London this year. The chief objects of the congress are to celebrate at once the jubilee of phonography (Pitman's system) and the tercentenary of modern shorthand. Mr. T. A. Reed is the chairman of the Jubilee Executive Committee, and Mr. Gurney-Salter the chairman of the Tercentenary Executive Committee. It is interesting to observe that Dr. Timothy Bright, a London physician, printed his "Characterie: an art of short, swift, and secret writing by character," in the year 1588. And he may be regarded as the founder of the modern method of shorthand.

French Lunatic Asylums.

The supervision of French lunatic asylums appears, if recent accounts be true, to be exceedingly lax. It will be remembered that a short time ago a man was released from an asylum, having been forty years previously confined by his relatives in order to secure his wealth. The escape of another man is now reported, who, although sane, was confined for a year in an ill-lit room, bound hand and foot. Such treatment is strictly forbidden by law, and the matron and two keepers of the establishment have been fined, and the medical superintendent condemned to a fortnight's imprisonment. Such regrettable and scandalous incidents would be impossible if any control were exercised by the authorities.

New Foreign Medical Journals.

A new French weekly medical journal commences with the new year. Its object is to assert the importance of provincial medical science and to assist in the decentraliza-

tion of French medicine, which it is considered is concentrated too much at Paris. The title is *La Province Médicale*, and it is published at Lyons.

The appearance is announced in Vienna of two new medical journals—*Klinische Zeit und Streitgragen*, edited by Prof. Schnitzler; and a weekly entitled *Internationale klinische Rundschau*, edited by Drs. Bela Weiss and A. Schnitzler.

The Late Professor Post.

Dr. S. Haynes writes to the *Med. Record* that in the winter of 1852–53 he witnessed the reduction of a dislocation of the cervical vertebræ by Dr. A. C. Post. The man was placed on the operating-table, and by means of extension and counter-extension, with a little manipulation, the dislocation was readily reduced. He adds that Dr. Post was known as a staunch temperance advocate, and says that it was currently reported among the students at that time that he had voted against the granting of diplomas to fifty students at the previous session on account of their intemperance.

Females and Women.

Dr. Williamson protests, in the *Brit. Med. Jour.*, against the common employment of the word female when woman is meant, and calls the editor to task for publishing a paper on "Some Functional Disorders of Females." He regards that subject as one covering altogether too much ground to be discussed in a short paper, and thinks it would have been better if the writer had called his paper one on disorders of women. Seeing the title, he says he read the article, expecting to find it a study in comparative physiology.

College of Physicians.

At the annual meeting of the College of Physicians of Philadelphia, held January 5, 1886, the following officers were elected:

President—S. Weir Mitchell, M. D.

Vice-President—John H. Packard, M. D.

Censors—Drs. Lewis Rodman, William Goodell, Alfred Stillé, and Samuel Lewis.

Secretary—Isaac Norris, Jr., M. D.

Treasurer—Charles Stewart Wurtz, M. D.

Honorary Librarian—James H. Hutchinson, M. D.

Recorder—J. Ewing Mears, M. D.

The Wealth of Families.

The physician is paid well, or otherwise, in accordance with the supply of money in the families among which he practices (says the *Med. Record*). There are about eleven million heads of families in this country. Estimating their incomes on the same basis as that of English tax returns, there are only about one hundred thousand families having annual incomes reaching $2,000, and only about thirty-five thousand having an income equalling or exceeding $5,000. Out of fifty-five millions of population, forty-five millions earn $15 a week or less.

Foreign University Intelligence.

Bern.—Dr. Demme has been appointed Professor in Ordinary of Pharmacology and Children's Diseases.

Bologna.—This University will celebrate its seven hundredth anniversary in the spring.

Bonn.—Dr. Franz v. Leydig, Professor of Comparative Anatomy and Zoölogy, will retire in April.

Freiburg.— Dr. Baumgärtner, formerly Professor of Pathology and Director of the Medical Clinic, died at Baden-Baden on December 11.

Faith-Cures by Water.

St. Petersburgh society has been somewhat interested in a medicinal water discovered by a Baron Vrevsky, and stated to effect marvellous cures. Owing to an official permission to continue the use of this water being necessary, the Medical Committee of St. Petersburgh caused it to be analyzed; and the result of this analysis, according to the *Official Messenger*, is to show that this famous and universal remedy is absolutely identical with the water of the Neva.

Philadelphia County Medical Society.

At the annual meeting of the Philadelphia County Medical Society, held on January 5, 1887, the following officers were elected:

President—Dr. J. Solis Cohen.

Vice-Presidents—Drs. W. W. Keen and E. T. Bruen.

Secretary—S. Solis Cohen.

Treasurer—L. K. Baldwin.

Censors—Drs. Joseph Hearn and De Forest Willard.

A Peculiar Method of Gynecological Examination.

The *Med. Record* is responsible for the statement that Omaha seems to have a gynecologist whose methods are decidedly unique.

He has a large, unwashed old dress of his wife's in his office, and all patients are directed to remove every article of clothing, and then to don this dress preparatory to ascending the table. While on the table, no effort to prevent exposure is made. All his patients are compelled to receive local treatment daily, and straight through the menstrual period as well.

Toys for Hospitals.

Seven years ago, the editor of *Truth* started an exhibition of toys, made by its readers, for distribution among the hospitals. At the last exhibition, over fifteen thousand toys were sent in for exhibition and distribution. The idea is a good one, and might well be carried out in this city, in connection with some of our charitable organizations. There is one hospital which treats or cares for children exclusively, besides other hospitals which have children's wards.

The Anatomical Institute, Vienna.

A magnificent building, which has been just completed at a cost of 460,000 fl., was opened early in October. The opening ceremony was performed by the Unterrichtsminister, Excellenz von Gautsch, assisted by the Professors of Anatomy Langer and Toldt, many other professors, and crowds of students. Notwithstanding the amount of work required for its completion, the whole has been successfully carried through in the short space of fifteen months.

Money for the Congress.

It is one of the important questions now how the funds are to be raised to help the Congress through. We would suggest to all who have the success of the Ninth International Medical Congress at heart, to at once send ten dollars for a ticket to Dr. John B. Hamilton, Washington, D. C., the secretary general, for the membership fee. This, if done now, will be a great help, and *all* should be willing to do this *now*, and save time and trouble, and also thereby uphold the hands of the executive committee.

Bacteriology in Barcelona.

The municipality of Barcelona has arranged to establish a laboratory of bacteriology, and to furnish it with the requisite appliances for all classes of investigations. It is to be under the well-known Dr. Férran, whose views were accepted much more generally in Barcelona than in Madrid. The measure was agreed to in the Town Council by a majority of twenty-five to three.

The Pasteur Institute.

The Paris Municipal Council have agreed to M. Pasteur's application for a 99 years' lease of 2,500 metres of ground adjoining the site already granted for his institute. The ground rent is fixed at four francs per metre.

Items.

—A child, aged five, died in Dublin recently from having swallowed a noggin of whisky administered by his father while intoxicated.

—The Swiss authorities will not allow a foreigner to practice even among his own countrymen in Switzerland without passing the State examination at Bern or Geneva; and this is by no means a matter of form.

—A new hospital for contagious diseases, having a capacity of four hundred and forty-eight beds, is about to be erected in Milan. In addition to the main building there are to be separate pavilions for small-pox, diphtheria, and typhus fever.

—The new Swiss alcohol law, conferring the monopoly of the production of alcohol on the State, contains a provision that no substances shall be used in distilleries which are not recognized as wholesome; from this category the potato is excluded.

—A correspondent writes to the *Medical Record* that he has used the ether-spray on several cases of strangulated hernia, one of two days' duration, with the best results. The operation was painless, and reduction occurred "spontaneously, or with slight pressure."

—A manufacturer of cheese in Prussia was endeavoring to improve his product, and, to this end, mixed the fresh cheese with about eight per cent. of mashed potatoes. The ripe cheese, however, looked suspicious; upon analysis the admixture was discovered, and the author of the new idea fined $12.

—In a valuable article in the *Va. Med. Monthly* on *fistula in ano* and phthisis, Dr. Archer Atkinson protests against the prejudice some physicians have to closing fistulæ in phthisical subjects. One drain, pulmonary, is sufficient, and he sees no reason for adding to the patient's depression by encouraging further loss.

Pallas Syringe.

[From the London Medical Record.]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche."

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten acres. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,

CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of recitations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

—LANDRETH'S SEEDS ARE THE BEST— NORTH, SOUTH, EAST, OR WEST!

PERFORATION OF VERMIFORM APPENDAGE.

BY J. M'F. GASTON, M. D.,

Of Atlanta, Ga.

This patient, being a very robust young man of thirty-two years, and prominent as Senator from the Thirty-fourth district of Georgia, gives importance to my report of his case. On the 8th of January, 1887, I was called to visit Mr. E. M. Word at the neighboring town of Decatur, who had been suffering since the night of the 6th from abdominal pain referred to the right iliac region, with indications of intestinal derangement. At the outset he complained of griping, and had some small evacuations from the bowels, but subsequently described his discomfort as of the nature usually attributed to spasm of the intestines, without further discharges of fæcal matter. In this state of things he sought the advice of his father, Dr. R. C. Word, who gave him two compound cathartic pills, and not being followed by any evacutions, in the course of some hours the dose was repeated, with the addition of two pellets of podophyllin. This failing of effect, enemata were resorted to without effect, and opiates were used to relieve the constant pain, referred now to the umbilical region. The contents of the stomach being dislodged by spontaneous vomiting, after taking a dose of castor oil, no other active medication was used until my visit, at 3 o'clock p. m., when I was expected to determine whether the developments pointed to intussusception or other impediment of the intestinal canal calling for an operation. I was accompanied by Dr. W. S. Elkin in the examination of the patient. There was a sense of tenderness on pressure over the ileo-cæcal region, with dullness upon percussion over a circumscribed area in right iliac fossa, and a perceptible density and firmness of the tissues without any well-defined outlines of induration. Over the rest of the abdomen there was nothing unusual noted. The pulse and temperature showed but slight departure from the normal standard. There was no disposition to take food of any kind; but thirst was constant, and led to the frequent use of small draughts of water without vomiting. In conferring with his father, we concluded to administer a combination of saccharated calomel and bicarbonate of soda, āā 10 grains, with ½ grain sulph. morph. every two hours, until three should be taken, and at longer intervals afterwards. One being given without annulling the abdominal pain, the inhalation of chloroform was carried to the point of complete anæsthesia and unconsciousness. In the meantime, preparation was made for the introduction of a long tube within the colon for employing an enema of warm water with soap, salt, and spirits of turpentine; and so soon as the patient aroused from the anæsthetic, he was placed in the knee-chest position, when a gallon of this fluid was thrown into the bowels by a Davidson syringe attached to the long intestinal gutta-percha tube. This was allowed to remain so long as he was able to retain it, not exceeding ten minutes, and was returned with considerable intermixture of fæcal matter washed out of colon in a fluid form, but no scybala or solid masses were discharged. Subsequent to this evacuation, hot stupes

with spirits of turpentine were applied over the abdomen, and two subcutaneous injections of sulph. morph. ¼ gr. with atropine $\frac{1}{120}$ gr. were made with intervals of an hour to secure composure, with the understanding that this hypodermic medication should be continued at intervals according to the indications from the pain. It was also determined that in case no purgation ensued from the calomel powders two tablespoonfuls of castor oil, with a teaspoonful of spirits of turpentine, should be given in the evening. This was taken and retained over four hours, when he vomited, stating that the taste and smell of the spirits of turpentine were perceptible in the ejected matter.

Up to this time there had been no thorough action of the bowels. and there was a doubt as to the impediment, but my mind inclined to the typhlitic origin of the trouble, while this acute suffering was not likely to result from ordinary cæcal inflammation.

A recent report in the REPORTER of January 8, by Dr. L. McLane Tiffany, of the troubles incident to perforation of the vermiform appendage, led me to think of the probability of this grave complication, and my attention was especially directed to this by the patient's complaint of intense pain along the penis in connection with the abdominal pains.

The circumstances pointing to the invagination at the ileo-cæcal valve lacked corroboration in the absence of vomiting, which is an almost invariable accompaniment of the strangulation of the intestine from intussusception, in like manner as in that of hernia. In the early ejection of the contents of the stomach we see nothing more than frequently occurs in an attack of colic, and the vomiting of the castor oil and spirits of turpentine after four hours of retention is nothing remarkable, so that there is simply the abdominal pain and arrest of intestinal action that create a presumption of the existence of intestinal invagination.

Viewed from the standpoint of the initial stage of typhlitis, originating in some unknown cause, I recommended the application of leeches over the ileo-cæcal region so soon as they could be obtained, and a special messenger was sent to Atlanta to procure the leeches. Unfortunately, only a few of the number brought could be induced to take hold, and yet the blood continued to flow from their bites for several hours after their removal. Our patient being an athletic, vigorous young man, this local depletion was especially indicated.

My visit at 8:30 a. m., on the 9th, revealed a general tenderness with tympanitic distension of the abdomen, while the dullness upon percussion in the right iliac fossa, and the sensitiveness upon pressure, were more marked than previously. It was evident that peritonitis was developing, and the pulse had become somewhat accelerated, with a temperature of 101° F., with increase of pain throughout the entire abdomen, in spite of the repetitions of the morphia and atropia hypodermically, at intervals of three or four hours. The calomel and bicarbonate of soda having been continued in the latter part of the night, an enema of warm soap water, with four ounces of castor oil and two drachms of spirits of turpentine was thrown up into the colon, with the injunction to retain it if possible. It so turned out that it remained during the whole day, and was only discharged at 9 o'clock that night, but without bringing any more fæcal matter than was supposed to be washed out of the colon. Even a second evacuation appeared to be the remnants of this enema, and afforded no evidence of relief to the obstruction.

In view of this torpidity and the persistence of the inflammation, local and general, of the abdominal cavity, it was advised to continue the calomel and bicarbonate of soda internally, and to apply belladonna ointment over the entire superficies of the abdomen with a thick fold of flannel wrung out of hot water and sprinkled with spts. turp., secured by a roller over the belly.

On the 10th, this being the fourth day of suffering, the patient was evidently enfeebled by the progress of the malady and the failure to take nourishment of any kind, insisting that he could swallow only water. This he was allowed in moderate quantities so often as he desired it, and it did not cause nausea or vomiting at any time.

The distension and sensitiveness over the entire abdomen was so intensified that I was not able to get the evidence of percussion satisfactorily, yet there seemed to be more resonance in the right iliac region than on the day before, while the general tympanites was more pronounced, with a saliency of the abdominal outline which was very apparent. The pulse had evidently lost in tone and increased in frequency, while the temperature had dropped to 99° F., with a haggard expression of countenance and dimming of the lustre of the eyes. When not under the full influence of the opiate there was an anxious unquiet manner that bespoke an impairment of the nerve-centres, and impressed me with the grave responsibility of deciding upon the further steps to be adopted without delay.

There was still no discharge from the bowels, and I recommended the repetition of the calomel and soda powders during the forenoon with another dose of oil and turpentine in the afternoon; and in case of no evacuation to resort to another enema of warm water with castor oil and spirits of turpentine in the night.

An effort was made to get colleagues from the city to see the patient during the day, with a view to a conference as to the surgical treatment that might be warranted, but owing to engagements of a pressing nature, neither of those to whom I applied was able to go, and the meeting was deferred until next morning, the fifth day of this disorder.

A conference with W. S. Elkin, G. G. Roy, and W. D. Bizzell, during the forenoon of the 11th, resulted in a conclusion not to undertake any operative measure, owing to the great vital prostration of the patient and the occurrence of a fluid fæcal evacuation about nine o'clock a. m.

In undertaking to administer chloroform, with a view to a more thorough manipulation of the abdomen than was admissible on account of the extreme sensitiveness to the touch, there was such manifest depression of the vital powers, with feeble pulse of 120 beats and temperature normal, as to cause us to desist from the inhalation of the anæsthetic, and to abandon the thought of an exploratory puncture over the ileo-cæcal region in search of pus in the deep structures, there being no fluctuation.

Brandy with milk and beef-tea was given freely internally, the hypodermic injections of morphia and atropia were continued to relieve restlessness, and a blister of cantharides plaster was placed over the belly.

Having left the patient in this most unpromising condition at 1 o'clock p. m., I received a message by telephone shortly after 5 p. m. that he had expired a few minutes previously.

Realizing that the proper understanding of the progress and result of this case rendered it important that an autopsy should be made, I prevailed upon my colleague and friend, Dr. R. C. Wood, the father of the patient, to intercede with his family for a post-mortem examination, which was granted.

Dr. W. S. Elkin assisted me in making the autopsy at 9 o'clock on the morning after his death, and I ventured to predict before the body was opened what might be expected, which diagnosis was confirmed by the results as here reported.

Upon laying open the abdomen along the linea alba, and making a transverse incision from the umbilicus to the right anterior superior spinous process, recent adhesions of the intestines to each other and to the peritoneal lining of the abdominal walls, indicated general peritonitis. On exposing the ileo-cæcal region, the cæcum was found covered with exudation, and presenting a dusky reddish dark hue, while the vermiform appendage was much thickened and discolored with a perforation about midway its length, and a large bean impacted near its connection with the cæcum, but its immediate entrance into the wall of the cæcum seemed to be comparatively free from turgescence or engorgement.

The portion of intestine below this knuckle was relaxed and empty, while that above was distended with gas, and yet the bowel was not completely occluded from the inflammatory thickening of its coats, but was rendered impervious by the angular relation of its walls. It will be remembered that in my report of a case of laparotomy some months ago, this doubling of the intestine upon itself was referred to as intercepting the passage of even gaseous matters through it in the same way that an India-rubber tube becomes occluded by being flexed at a sharp angle. The thickening of the coats of the ileum in connection with this flexion had been sufficient to arrest any free transit, and yet doubtless admitted of the passage of the fluid fecal matter which was discharged spontaneously on going to stool some eight hours before death. As there was no strangulation of the bowels, we are prepared to understand the absence of vomiting, which was inexplicable upon the supposition of intussusception or other entire constriction.

There was some effusion in the peritoneal cavity, but the undertaker had already thrown into the abdomen an antiseptic fluid before it was determined that an autopsy would be made, and hence no estimate could be made of the amount or nature of the exudation. It was evident, however, that the contents of the appendix vermiformis had escaped through the perforation and caused the general peritonitis.

The key to the peritonitis and to the vital depression from septicæmia was exemplified by the occlusion and perforation of the vermiform appendage, and a constriction in the ileum explained the obstruction, the gut being bent upon itself and much inflamed where it lay against the appendage. As has been stated, my diagnosis was verified by the autopsy, but unfortunately I had not the data for making this diagnosis until it was too late to accomplish what might have been

attained at a very early stage of this case by laparotomy.

The members of the medical profession who have had most experience in abdominal surgery and in diagnosticating the causes of intestinal obstruction will appreciate the difficulties in the way of a differential diagnosis within the first three days of the course of this case. While my attention was early fixed upon the cæcal region as the source of trouble, it was only after the indications of a septic nature and the consequent depression of the nerve centres, that I realized the probable existence of perforation of the vermiform appendage. At this stage of vital prostration there was no reasonable ground to expect any other than a fatal result of laparotomy; and no surgeon is warranted in operating under such untoward surroundings as were presented during the last thirty-six hours of the waning life of this patient. It is highly probable that laparotomy within the first twenty-four hours and excision of the entire vermiform appendage with suture of its line of separation, would have been attended with success. But with only such symptoms as accompany typhlitis of an aggravated character to guide my steps at that stage of development, I did not consider, nor do I now think such operation warrantable at this period of an unforeseen complication of intestinal obstruction.

ON EPILEPTIC BRAINS.*

BY FRANCIS X. DERCUM, M. D.,

Instructor in Nervous Diseases, University of Pennsylvania, and Pathologist to State Hospital for the Insane at Norristown.

The writer has thus far had the opportunity of studying twelve epileptic brains. Eleven of these have been already described in the "Report of the Pathological Laboratory of the State Hospital for the Insane at Norristown" for the current year, while the twelfth has likewise been described in the "Pathological Report" of the same institution for the year 1885.† It is not, therefore, my intention to give a detailed account of the convolutions of these brains, but merely to point out some striking peculiarities and to give expression to some of the thoughts which this study has suggested.

We have, in the first place, a notable tendency to the confluence of fissures, which is an acknowledged point indicating a low degree of cerebral development. This tendency is well marked in *every one* of the brains studied. In a number of instances the fissure of Rolando is confluent with the Sylvian fissure. In a number of others the Sylvian, interparietal, and parallel fissures are variously confluent. One of the most striking and most constant instances of confluence is observed in the parieto-occipital with the interparietal. It occurs completely in *seven* of the brains studied, and imperfectly in two others.

This tendency to the confluence of fissures is of necessity accompanied by an absence or lessened development of the normal arching or bridging convolutions. For instance, as is well known, the upper end of the parieto-occipital fissure is normally separated by the first occipital convolution of Ecker, the so-called *pli de passage supérieure externe* of Gratiolet. In the instances where these fissures are confluent this *pli de passage* is either entirely absent or so imperfectly developed as not to emerge upon the general surface of the brain.

As a result of the confluence of fissures, appearances resembling the conditions found in the brains of monkeys are occasionally simulated. This, again, is notably the case where the parieto-occipital and inter-parietal fissures are confluent. In the majority of instances in which this confluence occurs, the upper end of the parieto-occipital passes through the inter-parietal fissure, and terminates far beyond on the lateral surface, thus exactly reproducing the *external perpendicular fissures of the apes.* Occasionally this external perpendicular fissure is accompanied by a second fissure running in a parallel direction, and in one of the brains studied there were three such parallel external perpendicular fissures. It is probable that in these cases *one* of the fissures is homologous with the corresponding fissure in the apes, while the others are merely "*vegetative repetitions.*"*

Following the course of the external perpendicular fissure we come, in some instances, upon a well-marked Wernicke's fissure—*i. e.*, a fissure running more or less perpendicularly and separating the occipital and temporal lobes. In one of the brains the external perpendicular fissure and the fissure of Wernicke are so well developed that the occipital lobe is, as it were, almost lopped off from the rest of the brain.

In addition to such fissures as appear to

*Read before the Philadelphia Neurological Society, December 27, 1886.

†Also more fully in the proceedings of the Pathological Society of Philadelphia for 1885.

*The reader is referred to a communication by Dr. A. J. Parker published in the proceedings of the Academy of Natural Sciences, 1878, in which the *principle of "vegetative repetition"* of fissures and convolutions is pointed out.

be of purely morphological value, we have others which bear no analogies to the normal fissures of either man or the apes. Prominent among these are numbers of anomalous fissures on the occipital lobes, especially on the lateral surfaces. There is also a tendency in some of the brains to the formation of tranverse or perpendicular fissures on the frontal lobes. In one instance there are three such fissures present. Again, various fissures connecting the parallel, Sylvian, inter-parietal, and central fissures must be placed in the category. One anomalous fissure deserves especial mention. It is a short one-forked branch, passing from the Sylvian directly down into the temporal lobe. It cuts deeply through the first temporal convolution, and the gyrus surrounding it completely breaks up the anterior portion of the parallel fissure. Evidently these fissures have a special significance, which differs widely from that of the abnormal fissures which have homologies with those of the brain. To this significance we will shortly recur.

In addition to the two classes of abnormal fissures, these brains present striking facts of the under- and over-development of various parts. For instance, one brain presents an enormous over-development of the cuneus. The latter is so large that, instead of being wedge-shaped and small, it constitntes an enormous block of tissue, which is bounded below by a calcarine fissure depresssed beneath its usual level, and anteriorly by a parieto-occipital fissure, which in one hemisphere runs upward at *right angles* with the calcarine, and in the other actually *runs forward at an angle of one hundred and twenty degrees.* In the same brain the lateral surface of the occipital lobe is also much enlarged. The frontal lobes, on the contrary, are small, and the fissures constitute mere shallow depressions on the surface. Here, then, is an instance of enormous over-development in the occipital region with an absence of development in the frontal regions. In another brain the quadrate lobule is so enormously developed as to be the most conspicuous part of the mesial surface of the hemisphere. This over-development is also shared by the inferior parietal lobule. The cuneus, on the contrary, appears unusually small. The surface of the quadrate lobule is made extremely complex by a number of deep and intricate fissures. Again, in another brain we have a *pli de passage superiéure interne* developed up to the surface—a convolution which, as a rule, is developed only in the apes. Further, the various normal fissures of these brains frequently pursue aberrant courses. The Sylvian, the parallel, the interparietal fissures are frequently deflected from their average courses from the over- or under-development of the convolutions bounding them. The absence or small size of some of the arching convolutions are again conspicuous illustrations of under-development.

In summing up the above results, it is evident that we have, first, abnormal fissures which are purely morphological in their significance, and secondly abnormal fissures which are purely pathological in their meaning. To the category of the first belong those fissures whose homologues are found in the apes or monkeys, and of these the external perpendicular may be taken as a conspicuous example. To the category of the second belong those fissures in which no homologies can be demonstrated. In this connection, it is interesting to note that in the majority of the cases studied, sclerosis of the skull coëxisted. In almost every instance there had been a powerful hindrance to the growth and development of the brain. It is probable, therefore, that these anomalous fissures are the result of mechanical causes—*i. e.*, of growth within an unyielding and an abnormally small space. In the development of these epileptic brains, therefore, both pathological and morphological factors must have played a part. There can be no doubt, however, that the pathological factor must have predominated, and it seems, indeed, as though it must have been at the very bottom of the altered and aberrant growth. Certainly the various instances of the hypertrophy and of the under-development of parts admit of no other explanation.

The study of these brains is very suggestive in regard to the essential pathology of epilepsy. The cardinal feature of epilepsy is, beyond a doubt, a nerve-explosion, and whether this be a sensory, a motor, or a psychic explosion, does not in any way alter the case. Now, the nervous system is continually storing up force, or, what amounts to the same thing, its protoplasmic equivalent. In the normal condition force is emitted in a relatively gradual manner, and this gradual outflow is dependent upon the interaction of *all parts* of the nervous system. In other words, the entire nervous system is in a condition of equilibrium, and the action of any one part is restrained or inhibited by the action of all the other parts.*

* See "Facts and Deductions Bearing on the Action of the Nervous System," by Francis X. Dercum, M. D., Journal of Nervous and Mental Diseases, November, 1886.

Now, in order that this equilibrium may be maintained under the usual strains to which the organism is subjected, the nervous system must have a certain structure, which is the average structure, and which we have learned to regard as the normal. Now, in these epileptic brains certain parts are absent or poorly developed, others again are developed largely in excess, and others still are aberrant and bizarre. Surely it is not going too far to infer that in such a brain the maintenance of equilibrium must be confined to relatively narrow boundaries. In the normal nervous system there must be a certain play, or, if I may use the expression, a certain elasticity of equilibrium—a certain facility of readjustment between the different parts—and by means of which a *stable* equilibrium is secured. In a nervous system, however, where the parts are irregularly developed, and therefore badly adjusted, even slight strains may be sufficient to disturb the balance. The parts cannot yield or play upon each other, readjustment cannot take place, and some portion of the engine being, as it were, detached, suddenly runs down—*i. e.*, an epileptic explosion takes place.

The above inferences appear unavoidable, though the writer does not by any means wish to imply that all epileptic brains must have the flaring abnormalities of structure presented by the ones he has studied. These cases, however, were all confirmed epileptics, mostly epileptic dements; one suffered from epileptic mania and another was an epileptic imbecile. They certainly point out the importance of making a detailed study of convolutions in autopsies of all cases with a history of epilepsy.

FACIAL SPASM AND TIC-DOULOUREUX FOR WHICH NEURECTOMY AND NEURO-TENSION WERE EMPLOYED.*

BY GUY HINSDALE, M. D.,

Of Philadelphia.

I have the pleasure of asking your attention to the records of two cases of persistent trifacial neuralgia, and also a case of painless facial spasm. The two former were under the care of Dr. S. Weir Mitchell at the Infirmary for Nervous Diseases, and the last under the care of Dr. W. Sinkler, by whose permission they are brought before this Society.

* Read at the Philadelphia Neurological Society, December 27, 1886.

The cases are of interest from the fact that the first was treated by medicines pushed to an extreme limit; the second, failing to improve under medicines, was treated by exsection of the infra-orbital nerve; while the last was treated by stretching the facial nerve.

The cases are not reported because of any supposed rarity, or because they are in any way particularly remarkable; but merely to show what is the practice of the hospital, and to invite an interchange of views as to the relative merits of the treatments adopted.

Mrs. H., suffering with neuralgia of the right side of the face, entered the Infirmary for Nervous Diseases November 9, 1885. She is sixty-two years old, was born in New Jersey, and has always lived there. She considers her home dry and healthy and free from malaria. Her father died with phthisis. The patient herself has never had malaria or chills and fever, but had an attack of pleurisy fifteen years ago, associated with severe cough. This has been her only severe illness. She has been married forty-two years, and has had fourteen children, of whom two only are living. Eighteen years ago she experienced a severe shock in the loss of six children from diphtheria within a period of four weeks: she had previously lost others in their infancy.

Twenty years ago the patient began to have twinges of pain in the lower jaw. Four or five years ago she suffered from attacks of neuralgia of the right side of the face two or three times a year: these attacks lasted from one to three months. In 1884 she had four or five attacks, one of which lasted two months; though quite weak, she was not confined to her bed at any time. Fever sometimes accompanied the attacks, without any chill, but with a cold sweat when the pain was very severe.

A year or two ago the pain occurred at any time during the day, but passed away at evening, upon retiring and remaining quiet. In April, 1885, the pain began to be worse at night, but it cannot be said that any special hour was observed. Cold air, eating, or drinking very hot drinks, motion in bed, bad news, mental trouble, aggravated the pain. Rest, peppermint essence dropped on the tongue, sweating the face with hot bricks dampened with whisky and wrapped in cloth, did for a time relieve the pain.

The treatment adopted consisted of rest in bed, good feeding, and the use of an ascending galvanic current. This was applied to the right side of the tip of the tongue and to the right side of the lower jaw for fifteen

minutes, morning and evening. This was the chief locality of pain. Cod-liver oil, ʒiv., and tinct. aconiti rad. were given after meals. The aconite was gradually increased in quantity until, on the nineteenth day, she was taking seventeen drops four times a day. Elixir of iron, quinine, and strychnia, one teaspoonful thrice daily, was then added. The early doses of aconite, of two and three drops each, produced some tingling of the fingers and tongue, with numbness of the right arm and hand; the larger doses did not produce any more pronounced symptoms. The pulse varied in frequency from 67 to 82 per minute. Hydrochlorate of cocaine in four per cent. solution was applied two or three times a day to the painful spot on the right side of the extremity of the tongue; this gave relief for about twenty or thirty minutes. Failing to control the pain notwithstanding this persistent use of aconite, on December 1 fluid extract of gelsemium was used; four drops were given thrice daily, and the dose gradually increased until the physiological effect was produced. Hunyadi water was given occasionally, and massage of the spine was adopted. On the following morning a blister was applied to the right temporal and zygomatic region; a cold-water dressing containing half a grain of morphine was used. The blister had caused considerable local irritation by evening, and the pain in the face and tongue was relieved; the pain, however, recurred the next day, with dull aching in the forehead and across the eyes.

Lunar caustic was applied to the right side of the tip of the tongue on December 4; the area cauterized was about half an inch square. Electricity was suspended for three days. Subsequently applications of nitric acid were made to the tongue.

Swimming of the forehead, dimness of vision, and drowsiness accompanied the increasing doses of gelsemium. The dose of gelsemium was increased for twenty days, until the patient took thirty-six drops of the fluid extract three times a day; there were then dizzinesss, headache, some drooping of the eyelids, but no pronounced symptoms or apparent benefit from the medication.

I have prepared a chart from the careful daily records taken by Miss Kenealy, the chief nurse of the Training School, showing for each day the treatment, the pulse, respiration and temperature, and subjective symptoms.

At the end of seven weeks the patient was discharged, although still suffering at intervals from pain in her tongue. The facial pain was very much less than when she applied for treatment. The use of nitric acid on the painful spot in the tongue was advised.

At the end of six months the patient was still suffering with neuralgia, but not so severely as at first.

Mrs. E. H. H., æt. 64. No hereditary nervous disease. She was delicate in early life, and as a child had chills and fever for three years, but never had any serious illness. Thirty years ago she began to have pain in the infraorbital, and then in the supraorbital region, darting and of intermittent character. It was serious enough to confine her to bed. The attacks were influenced by weather and exposure. Sometimes attacks came on every few days; sometimes not once in three or four months. Exposure to draught, to cold, or to wind, would bring them on. Warmth would relieve the pain. Liniments failed; warmth always gave the most relief. Duration of attacks, one to seven days, or even a month. For seventeen years she had noticed a singular sensation in the right nostril, as though pierced by a dozen needles. Pain extended to the cheek and under the eye. The patient for four years had a severe attack, lasting the whole month of February. It would take an entire month to recover from its effects.

November 21, 1885, the pain was constant and more or less severe, both diurnal and nocturnal, and she was kept awake a great deal at night. Teeth had been extracted from both jaws before applying for treatment.

A general tonic treatment, consisting of massage, lactate of iron, cod-liver oil, and malt, was adopted, and galvanism was applied gently to the side of the face. Blistering, morphine, quinine, arseniate of iron, and bromide of lithium, were applied in succession, without relief.

Finally, the infra-orbital nerve was exsected by Drs. Hunt and Morton, a small portion of the floor of the orbit being also removed. The patient suffered a good deal of pain in the same spot as before: this, however, subsided to a certain extent, and two weeks after the operation she returned to her home in Maryland. While not altogether free from neuralgic pain, she considered herself much more comfortable than before, and greatly improved in general health. Nine months later she was reported to be in good health, with little or no neuralgia.

In a case of painless spasm of the face, Dr. W. W. Keen has recently operated on

a patient at the request of Dr. Wharton Sinkler. The patient had twice been paralyzed. Five years ago the right eyelids began to twitch, and in six months the whole face and the platysma were incessantly in spasm, which was increased by mental or muscular effort; later, this was accompanied with constant pain. In June, 1884, the right infra-orbital nerve had been resected, with partial relief for only six weeks. Not long after this the twitching extended to the right side of the body and to the leg.

April 2, 1886, Dr. Keen laid bare the trunk of the nerve, using an electric current to facilitate its discovery. The nerve was then stretched; the force used was just short of enough to lift the head. Total paralysis of the face followed, with relief not only of the spasm of the face and neck, but also of that of the side and leg.

Stretching of the facial nerve for cramp had been performed by Baum and Schüssler in 1878, Eulenberg, Godlee, Hahn, and others.

In Eulenberg's case, stretching the nerve was resorted to after a neurotomy of the supraorbital had failed; a tolerably severe paralysis resulted, lasting several weeks, but finally disappeared. In Godlee's case, twenty-eight months after the stretching the favorable result remained. In Hahn's case there were spasms over the whole right side of the face; after the operation, which did not induce any paralysis, there was only partial benefit. Two years after the operation the cramps persisted.

In 1880 Langenbeck stretched the temporo-orbital division of the left facial nerve, and also a branch going to the zygomatic muscles. After twelve days the eye remained wide open, paralyzed; the angle of the mouth drooped. Two months later paresis of the left side of the face was still apparent; return of spasm. After four months the spasm was as severe as ever, and the paresis was apparent. The patient thought the paralysis the lesser evil of the two.

In a case of Godlee's in which there was painful spasm of both sides of the face, the left facial was stretched; paralysis followed. Four months later the right nerve was stretched. Several months after this the paralysis had disappeared, and the condition was as bad as before the operations.

In Putnam's two cases the results were not encouraging.

In a case of Southam's, in 1881, the paralysis vanished in sixteen weeks; two and a half years later the good result was still apparent.

Dr. Zesa's summary of nineteen cases gave permanent good results in three, doubtful in two, considerable improvement in four, failure in ten. In ten cases temporary benefit followed the operation.

AN ANALYSIS OF THE OCULAR SYMPTOMS OBTAINABLE IN EPILEPSY IN THE MALE ADULT.*

BY CHARLES A. OLIVER, M. D.,

Visiting Physician and Ophthalmologist in the State Hospital for the Insane, Norristown, Pennsylvania; Ophthalmic and Aural Surgeon to St. Mary's Hospital, Philadelphia.

The clinical material for these observations was obtained at the State Hospital for the Insane at Norristown, Pennsylvania. The report embraces a study of all the ophthalmic symptoms that could be gotten from fifty male adult epileptics, without reference to any past etiological factor or present mental condition. This method was pursued for several reasons, most prominent being:

1. A special form of symptomatic disease was taken in preference to any mental condition, because similar mental states may be present in the many and *bizarre* forms of nerve-lesions, making and hiding the true significance of the objective symptoms peculiar to any one disease to such an extent as to render differentiation impossible.

2. A definite variety of disease was chosen, so as to avoid obtaining mere percentages of the ophthalmoscopic signs (which, as a rule, have been limited to an arbitrary designation of the tint of the optic disk and the size of the retinal vessels) of the total number of cases occurring in one asylum—practically giving, if at all correct, a *resume* of the different varieties of optic-nerve color and retinal-vessel size of the gross amount of residents of that asylum; an answer which is liable to alter at any time through change of number of patients and character of mentality, or to be totally diverse from the results obtained by another observer placed in a different situation.

3. A large percentage of similar cases was taken. This was done so that the different mental states which are seen during the course of any *one* disease might be united into a theoretical average case, which would represent a typical example of the physical and physiological conditions of that disease.

4. Males were used. This is important,

*Read before the Philadelphia Neurological Association, December 27, 1886.

for, by the exclusion of the female subject, any errors that might arise from additional ocular changes dependent upon diseases which are peculiar to the sex are avoided.

It may be interesting to know that native American stock has been used. There is nothing absolutely important in this selection, because, by reason of many obvious causes, a true American type of man has not as yet been established among us; yet it was intentionally done, so that results obtained from subjects born on American soil could be contrasted and compared with statistics of foreign-born population, in order to see whether the data would exhibit any decided peculiarity in ratios.

OBSERVATIONS AND CONCLUSIONS.

1. Direct vision for form, as a rule, normal in both emmetropia and corrected ametropia.

2. Accommodative action normal in due proportion to age and refractive error.

3. Visual fields for form and color reduced from one-third to one-twentieth of normal areas.

4. Visual fields for form and color regularly diminished without any indentations or scotomata.

5. Order of color-field follows the regular physiological sequence, without transposition or reversion.

6. Subnormal color-perception to a slight extent, as evidenced by faulty selection of delicate tints and shades containing low percentages of green and red.

7. Pupils are, as a rule, equal in size and alike in shape.

8. Irides freely and equally mobile to light-stimulus, accommodation, and convergence.

9. Extra-ocular motion intact in all directions. The presence of insufficiency of the interni in the majority of cases is readily explained by association with existing H V Ah, and probably has no relation to the epileptic condition.

10. Optic disk superficially over-capillary, with a decided grayness in its deeper layers, showing a low grade of incipient optic-nerve degeneration.

11. Scleral ring rather more sharply cut and broader, especially to the temporal side of the disk, than in the healthy eye; this being probably due to a slight shrinkage of lowered nerve-tissue.

12. Fibre-layer of retina increased in thickness, as evidenced by dense and coarse massings of striation extending in all directions from the disk, these being more particularly marked in the superior and inferior portions of the eye-ground, even hiding the edges of the disk itself in many instances.

13. Retinal vessels large in size and carrying rather dark-colored blood, this being more pronounced than usual with the veins.

14. Retinal veins exceedingly tortuous, and in a few instances pulsating.

15. Retinal arteries frequently wavy and sometimes tortuous, especially the temporal and macular twigs.

16. Retinal lymph-channels visible in the majority of cases, particularly seen along the larger vascular distributions and at the vessel-entrance as glistening and yellowish-white opacities.

17. No other visible changes of any significance throughout the eye-ground, except a granular condition of the choroid in the macular region.

In addition, it may be mentioned that, as far as possible, nearly all of the deep and superficial reflexes were obtained throughout the body. These, as a rule, were above normal, and presented some curious anomalies, which will be reserved for a later publication.

As was to be expected among this class of patients, many of the subjective signs were negative; but, withal, sufficient data have been produced to warrant proper conclusions in this direction. The results obtained from the study made of the visible ocular changes are of special value, and may be cited as of sufficient importance to be useful in diagnosis.

Thanks are due to Drs. Charles A. Woodnutt and Henry Sykes, assistant resident-physicians, for good work and carefulness displayed throughout these researches.

1507 *Locust street.*

Medical Societies.

THE PHILADELPHIA NEUROLOGICAL SOCIETY.

A stated meeting was held December 27, 1886; the President, Dr. S. Weir Mitchell, in the chair.

Dr. Guy Hinsdale read a paper entitled

Facial Spasm and Tic-Douloureux for which Neurectomy and Neuro-Tension were Employed. (*See page* 166.)

DISCUSSION.

The President, Dr. S. Weir Mitchell: "I have several points to make with reference to these cases. The woman operated on by

Dr. Keen I have seen within the past few days, and she presents no paresis of the face at all. As yet, the case is a perfect success. She is entirely free from any twitching. Her case recalled others, and in looking over my note-books I found that within the past twelve years I had seen fifteen cases of painless tic, in none of which was the slightest relief afforded by any method of treatment. It so happened that shortly after Dr. Sinkler's case was treated so successfully, Mrs. G., aged forty-nine, the widow of a physician, a very intelligent woman, consulted me. She stated that her tic had begun about three years ago. It first appeared under the eye, where it nearly always begins, although I may say that as yet the history of these cases is not complete. Then the twitching appeared in the cheek, which, as a rule, has been the point next attacked in my cases. The spasm afterwards extended to the mouth. In those cases in which it became general it extended beyond that, and in the last case that I have seen the levator muscles of the ear were involved, so that the ear was drawn upward every time that the face twitched. But extension to the neck or more distant parts is seen at times in rare cases.

"In Mrs. G. the spasm is very violent, and she described it by saying that 'the whole side of the face migrated under the left ear and stayed there awhile.' The length and endurance of the spasm were remarkable. She had from ten to fourteen attacks every minute. They were pretty regular. At certain times she was comparatively free, but scarcely five minutes passed without twitching.

"I observed in this case, as in some others, a certain amount of appearance of paresis on the affected side of the face—that is to say, the muscles on the sound side of the face appeared to predominate. I have so far been unable to observe any difference in the electrical reactions of the affected muscles. Perhaps more careful observation will show some change. It has been suggested to me that this paresis was the result of fatigue; but, as we know, in most spasms the muscles become larger and stronger, and do not present evidences of fatigue.

"In this case I began to think whether there was not something which had not been done which might give relief. The idea of weakening the facial nerve or its branches by freezing suggested itself. If I had reflected a little I should have recognized the fact that it is impossible to affect the deeper nerves in this way. Freezing by vapor-jets applied to the surface acts very little beneath the skin. I have tried this by putting the finger in the mouth and trying to freeze through the cheek by means of the rhigolene spray. I have never succeeded in producing more than a slight chilling. In this case I have on sixteen occasions frozen with the rhigolene-jet a large portion of the skin of the cheek, sometimes covering the whole of the side of the face, taking care to protect the eyes and to prevent the inhalation of the vapor.

"The result has been an interesting and a curious one. The very first freezing, like all the subsequent ones, brought on instantaneous spasm. The moment the jet struck the face there was violent twitching. When freezing was effected the spasms ceased and did not return for many hours. This result surprised me very much, and it appeared that while I was attempting to accomplish the result in one way I had done it in another.

"Under these daily freezings this case has gained so far as to pass days without more than such rare twitches beneath the eye as excite no attention. Enough has been won to satisfy her if the gain should last, as to which I will report.

I observed that a vigorous freeze over the points of nerve exit was better than a general freeze. I am about to try if localized freezing by ice and salt, or other means which act more deeply, may not answer. The influence *seems* to be exerted through the sensory nerves, from which possibly arise also the impressions which create these spasms. With my remembrance of former cases, I cannot say that I feel hopeful as to the remote future of the present one.

"I have tried the same plan of treatment in a second case of nine years' standing. She came to me some years ago, but, as I knew of nothing that would afford relief, I refused to treat her. I sent for her ten days ago, and began the use of the rhigolene spray. She too has slight paresis. The face is apparently pulled to the right, the spasm being on the left side, which is the side commonly affected. The results obtained with the individual freezings are practically the same as in the first case. The touch of the spray brings on the spasm. When the part is frozen the spasms remain absent for a considerable length of time, although not so long as in the first case. The period varies from half an hour to two hours. Under this plan of treatment the attacks have diminished in frequency and in intensity.

"This is as far as I have gone, but I thought it well to bring this matter before

you, for some of you may have one of these rare cases under observation and may desire to try the same experiment. As we know of no method of treating these cases except by operation, I consider it perfectly proper to try the effect of rhigolene. After the spray has been used for some days, care must be exercised that a slough is not produced. I have never had a slough, although I have made the skin very sore. This has led me to think that possibly the good result was due to counter-irritation, and I shall not be satisfied until I have tried extensive counter-irritation over the origin of the facial nerve in some suitable case."

Dr. J. Madison Taylor: "I have had under my care a case in which a severe spasm of the right side of the face had been present for twenty years. The woman was nervous, and came of a family, many members of which were in a general way nervous, yet quite strong and robust. The spasm, although very annoying, was not sufficiently marked to call for special treatment. About fourteen months ago the youngest daughter of this woman passed through a severe attack of typhoid fever. The mother, from nursing the child, became very much exhausted. Then the spasm grew worse, and was at times sufficient to shake the head. When the child became convalescent the mother was taken with the disease and had a severe attack, with high fever and delirium for six days. Upon her recovery from the typhoid fever the spasm had entirely disappeared, and to the present time, a period of ten or twelve months, there has been no return. It is interesting to note the curative effect of a severe illness on this intractable disorder. Hers was a veritable purgation with fire."

Epileptic Brains. (*See page* 164.)

DISCUSSION.

Dr. Charles K. Mills: "The specimens presented by Dr. Dercum have great value. It is, in part at least, by studies of this kind that we will eventually discover the basis of epilepsy and of some forms of insanity. All genuine investigations are practical, and in studies of this kind an outcome of good is evident, even from the practical as it is ordinarily regarded. Of the many classifications of insanity which have been attempted, that of Dr. H. M. Bannister, of Illinois, is, to my mind, the best, although open to some criticism. His classification is into first primary, and next secondary insanities. Under primary insanities he ranges—

"1. Teratological forms dependent on original structural defects.

"2. Pathological forms dependent on alterations due to disease.

"3. Mixed forms, generally pathological, but in part, probably, due to original structural defect.

"Under his first head of teratological forms he embraces cases of idiocy, imbecility, and what he chooses to term pseudo-paranoia. The point is that these are cases which can only be demonstrated through morphological or teratological conditions, such as are present in the brains exhibited this evening. By studies of the kind made by Dr. Dercum we are helped towards a fundamental understanding of insanity, and therefore towards better systems of classification. In regard to some of the apparent hypertrophies present, the idea suggests itself that these may be due not so much to overgrowth as to lessened resistance of the bony envelope.

"These studies are but the beginning of a great work. Valuable as this work is, it is but the pioneer work: the study of abnormal cerebral surfaces. Before long, these investigations will be carried below the surface, and will be histological as well as researches in gross anatomy."

Dr. J. Madison Taylor: "It is well known that in most of the subjects of the convulsive disorders of childhood there are found distinct evidences of rickets. Some writers have said that at least thirty per cent. of children with convulsive disorders present marked rachitic changes. Gowers states that in fully ten per cent. of all epilepsies rickets is a predisposing cause. This would seem to bear upon the subject of brain-changes due to faulty bone-growth."

Dr. J. Hendrie Lloyd: "I would ask Dr. Dercum, with reference to the onset of the epileptic symptoms in these cases, and more particularly as to the form of insanity which they presented, whether in all of the cases the disease was due to hereditary abnormality of development, or whether some presented acquired forms of insanity?"

Dr. Francis X. Dercum: "In many of these cases the history was obscure. Ten of the twelve cases were ordinary epileptic dements. In one case, that which presented the large cuneus, the patient was an epileptic imbecile, and had been so from early childhood. The other specimen is from an epileptic maniac. He presented attacks of epileptic fury. It seems to me that our notions of epilepsy are not altered by the different forms under which the disease presents itself: whether it manifests itself by an intellectual or emotional explosion, as in mania, or by a motor explosion, as in the

convulsions of ordinary epilepsy. We may find, as Gowers points out, cases where there is, instead of an explosion, a sudden arrest of all the processes. Again, the condition might show itself simply by the epileptic aura. There might be a sensory explosion without any motor disturbance. We should not limit our idea of epilepsy simply to the motor disturbance. The point in epilepsy seems to be that the normal interchange of function between the different parts is not kept up, this being rendered impossible by the abnormal construction of the parts. They are out of proportion to each other."

Dr. Charles A. Oliver read a paper giving

An Analysis of the Ocuiar Symptoms Obtainable in Epilepsy in the Male Adult. (*See page* 168.)

DISCUSSION.

Dr. Louis J. Lautenbach: "The subject which has been discussed by Dr. Oliver has been for the past three or four years worked upon by myself, both among male and female subjects, and among those not insane as well as among the insane; the cases have been both from hospital and private practice. Within the past week I have seen three patients with the ordinary epileptic symptoms. One of these had the typical ground which Dr. Oliver mentions. This was a case of idiopathic epilepsy. In another case, supposed to be one of syphilitic epilepsy, the eye-ground was different. In the third case there was still another picture, and in this instance the convulsions were due to the presence of a brain-tumor.

"It is an interesting as well as an instructive fact that there is a close resemblance between the eye-ground in a case of imbecility and that in a case of epilepsy; so far as I know, there is no essential point in which they differ.

"There is one point which Dr. Oliver has not mentioned that I have noted, and that is that in perhaps one-third of the cases examined, and especially in those seen in insane hospitals, the macular region presents a red granular appearance, and, in addition thereto, the macula itself was of a dull red color. I have not observed the darkness of the color of the blood, to which reference has been made.

"Gowers states, as the result of the examination of a thousand cases of epilepsy, that there is only one condition that appears to be somewhat frequent in these cases, and that is that the arteries and veins appear to be equal in size. It is strange that a careful observer llke Gowers has not noted the thickening of the fibrous tissue of the retlna which has been described by Dr. Oliver, and which is usually the first thing that is observed upon examining the fundus. In examining these cases I was struck with the frequency of high grades of hypermetropia, the proportion being greater than is observed among healthy individuals.

"There is another point of some interest, and that is that in long-standing epilepsy, where the attacks have been very frequent or severe, it frequently happens that the nerve presents very marked signs of degeneration, the atrophy being decidedly advanced, the direct form vision being well preserved."

Dr. Francis X. Dercum: "The use of the ophthalmoscope in epilepsy for diagnostic purposes I regard of comparatively slight value, for the diagnosis is usually made with ease from the history. The chief value is the light which it throws upon the pathology. Other things being equal, there is a certain correspondence between the condition of nutrition in the retina and the nutrition of the cerebral tissues. There is a certain amount of agreement between the opthalmoscopic appearances and the microscopic appearances of the brain-tissue. In one case of epilepsy in which Dr. Oliver examined the eye-ground, the patient subsequently died, and section of the brain showed changes similar to those found in the eye. There was a similar tortuosity of the vessels, a similar infiltration of the sheath of the vessels, and a general increase in the neuroglia."

Dr. Charles A. Oliver: "I am not now prepared to give any data in reference to the similarity of the eye-grounds of the imbecile and the epileptic, although I am pursuing investigations among the imbeciles at the Norristown Hospital for the Insane. Also, as I have before noted, I have carefully avoided any endeavor to make any differential diagnosis as to the causation of the convulsions. Inequality of pupil independent of local adhesion can be readily understood when differences of vision and accommodative action dependent upon refractive error, etc., which are so often seen in the two eyes of the same subject, are considered. These were carefully studied and purposely excluded, merely giving the pupillary reactions, sizes, and shapes, *as a rule*, although in a number of instances, especially where there was unequal contraction of the visual fields, I found some curious errors in the innervation arcs of the irides. In reference to the occurrence of high degrees of hypermetropia (varying from four to five dioptrics),

I must say that I have not found this to be the case, at least in those subjects that were at my disposal. The fact that the amount of grayness of the disk in some instances seems to bear no absolute relation to the amount of nerve degeneration—as was curiously shown in a series of observations made some years ago upon young, seemingly healthy males, in which I found that those nerves which were apparently extremely gray had excellent quantitative color-perception, while some some of the nerves which appeared of good healthy tint had not as good (none of these cases making a single mistake in Holingrein loose-wool selection, and all having perfect acuity for form—) is curious, although it must be admitted that the amount of vision and color-perception, with degeneration of nerve tisssue, is dependent upon the squeezing or atrophy to which the nerve is subjected. Those of Gowers' observations which were made during or immediately after a convulsive attack were extremely difficult to manage, although limited to cases in which the seizure began locally. His assertion that during the intervals of the fits there are no abnormal ophthalmoscopic appearances can, I think, be hardly borne out. In framing the conclusions which I have presented, I have grouped all of the symptoms, both subjective and objective, into an average case, hoping thereby to obtain a somewhat typical picture. The peculiarities of the eye-ground seen in the cases I have studied—those of long-standing attacks of frequent occurrence—are most probably explained by the presumption that every convulsive discharge leaves an additional pathological condition, by which the objective appearances of a low and chronic form of retinitis and perivasculitis, associated with dirty red-gray degeneration of the optic nerve, are at last established as the visible living results of a similar process which has been taking place within the intra-cranial substance, and which may be readily seen post-mortem by careful microscopic examination."

Dr. Granville Faught exhibited, by invitation, a new Milliampéremetre, made by Waite & Bartlett; also a pole-changing electrode-handle.

Dr. Charles K. Mills exhibited Rudisch's new portable galvanic battery.

Adjourned.

—Health was the first question considered by the ancient Greeks. Now, it is the doctor's bill they consider most. Then they took exercise to preserve their bodies. Now they take patent pills, or get you for your bills.

NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, January 4, 1887. C. L. Dana, M. D., President, in the chair.

Dr. W. H. Porter presented the knee-joint and spinal cord in a case of spinal arthropathy, and the spinal cord in a case of acute tabes dorsalis of six weeks' course.

Note on Aphasia with Reference to the Loss of Nouns.

Dr. Putnam Jacobi read a paper on that form of aphasia in which the defect is limited to the loss of nouns. Seventeen cases out of a total of one hundred and sixteen anlayzed offered this peculiarity, which had not failed to attract the notice of authors. Several explanations had been offered, none of which seemed, to the writer, completely satisfactory. Anatomical data were not at present sufficient to throw much light on the matter further than to demonstrate that the symptom was probably always associated with diffuse, and not with local, lesions. These lesions could not fail to lie on the sensory side of the speech mechanism, and for reasons detailed at length in the paper, must especially involve the paths between the auditory and visual centres, through which the auditory impression or sign of the object became habitually associated with the visual impressions. The writer maintained that the act of speech always involved an entire proposition, framed in the supra-sensory concept centres—probably the superadded convolutions of Broadbent. This proposition constituted a verbal conglomerate; a unity to the mind expressing it, whatever the number of seperate parts into which it might be broken up. Such actual verbal conglomerates remained in many primitive languages, as that of the Greenlanders and North American Indians, where entire sentences were often inflected like a single noun or verb. In our languages the conglomerate or proposition to be expressed is composed of the reminiscences of auditory signs which have become fused with similar reminiscences of visual impressions of things and their relations. If the visuo-auditory paths are interrupted, the signs or names of things will be dislocated from their habitual association with the other characters of such things, while the visual impressions themselves remain, and enter directly into the verbal conglomerate. All other parts of speech than nouns, expressing complete intellectual relations, and although remotely connected with impressions registered in the visual centre, are immediately associated only with the

processes and registrations of the supra-sensory or intellectual centres. While these are intact, therefore, and unless focal lesions have altogether obliterated the memory of language, the speech of relations will be remembered and revived in expression. The objects which are involved in the relations of the conglomerate proposition will no longer be revived in consciousness by their names, but by means of their visual impressions only. These can be expressed by gestures, mimicry, or paraphrases, the loss of the auditory sign thus compensated.

Peripheral Neuritis and the Painful Paralyses of Early Life.

Dr. H. D. Chapin read the paper, and said that there had been great scarcity of autopsies in comparison to the frequency of paralyses in children. For that reason a very careful clinical study was necessary, interpreted in the later knowledge of anatomy and physiology of the central and peripheral nerves. The writer had met an atrophic form of paralysis differing at its inception, development and result, from the spinal paralyses with which he was familiar. Most of the autopsies had been made many years after the paralysis, when death had taken place from some other cause. There having been but few autopsies in proportion to the number and variety of cases of paralysis, there seemed rather a slender basis for the theory of exclusive spinal paralysis of childhood. Laborde's case is mentioned where a tabetic neuritis existed with sclerosis of the antero-lateral horns, while the ganglion cells were found normal. Robin's case was cited, where no lesion of the cord was discovered. Such a case would show that paralysis is not necessarily always spinal. Barwell's theory was incidentally mentioned. He claimed that infantile paralysis is purely peripheral, involving the ultimate fibrillæ of the nerves among the muscular elements. Later, Leiden advanced a more rational explanation when he considered that in atrophic paralysis there may be neuritis with spinal cord lesion, and that instead of such forms of paralysis always originating in the spinal cord, they may have their beginning in any part of the motor apparatus, then spreading to other parts, or remaining limited to the part first affected. Leiden claims that where complete recovery takes place the morbid processes always remain peripheric. Leiden's theory is accepted by the author of the paper as affording satisfactory explanation for certain cases that he has observed clinically. The histories of three cases were given, in which paralysis was gradual at the onset, and attended by great and persistent pain. Pain was one of the most marked symptoms, and principally at the extremities—legs and feet. Most of these cases lasted several months, and then, to the surprise of the writer, slowly recovered. Atrophy was present. One of the cases appeared strongly rheumatic. In the other two the cause was uncertain. Malarial poisoning appeared to to be able to produce a more or less severe form of multiple neuritis resulting in paralysis. The history of a mild case was given which recovered under quinine.

Several cases were related in which children with malarial fever were seized with painful paralysis, lasting in one case over four months, followed by recovery. A possible explanation of pain is that it is due to the marked general congestion of the gray matter of the spinal cord. The author stated that in his cases, and others like them, there were no other symptoms showing irritation in the deeper parts of the cord. The general congestion or myelitis should cause bladder symptoms, bed sores, and other disturbances. Histories of two cases of lead paralysis in young children, seen by the author, were given. The lesions were regarded as largely peripheric. Cold usually attacks by preference the peripheric system of nerves. The loss of power sometimes following rheumatism is also probably of this nature. Any morbid blood condition appears able to produce a peripheral paralysis in early life, particularly with acute infectious diseases, especially diphtheria. The lesion in diphtheria is now known to be largely peripheric.

The object of the paper is suggestive, not dogmatic. The author has gladly availed himself of recent studies in peripheral neuritis tending to throw light upon some of the paralyses of children, which have caused much perplexity. The great differences in the clinical behavior of paralyses in early life, in duration and curability, must admit of different anatomical and pathological explanations.

Dr. M. Allan Starr did not know of any recorded case in a patient under twenty-four years of age, in which a lesion of a peripheral nerve had been found at autopsy, which would account for the paralysis; and while there was great probability in the statements made by the author, they yet lacked confirmation by autopsy. The points had been brought out very well with regard to the distinctions between peripheral neuritis and anterior polio-myelitis, but he would take exception to what had been

said regarding the rapidity of the onset. There were many cases of acute onset of peripheral neuritis, the patient having fever and chill, and the limbs within twenty-four hours becoming entirely immovable. Too much attention could not be given to the usually great tenderness in the muscles and nerves in multiple neuritis.

Dr. Rudisch said that he was the first to observe, as long ago as eight or nine years, a form of polio-neuritis leading to paralysis and atrophy, and which followed affections of the joint, often so-called rheumatic affections. We now saw often enough an affection of one or more joints with inflammation followed after a while by paralysis, usually curable.

Dr. Fisher said a girl, thirteen or fourteen years of age, was brought to the dispensary with the history that one morning, after taking cold, she woke up with paralysis of the upper and lower extremities. At that time she had only paralysis in one leg, which he supposed, without thought of neuritis, to be ordinary polio-myelitis. Rapid improvement took place, and she recovered within six weeks, and the minister who brought her reported the case as one cured by faith. Dr. Fisher was unable to say whether the case was an affection of the anterior cornua or one of multiple neuritis.

Dr. Sachs thought he should not be influenced too much by the present fashion, and call all or most of the cases formerly regarded as polio-myelitis cases of multiple neuritis. Referring to one of the cases related in the paper, and the symptom of pain, he said too much stress should not be laid upon it unless it was severe, persistent, and located distinctly along the tract of a peripheral nerve.

Dr. Leszynsky regarded pain as a prominent symptom of neuritis, absent in the majority of all of the cases of simple polio-myelitis. The pains present in some of Dr. Chapin's cases reminded him of the pain from straining of the tendons of the extensor muscles which had been for some time in a paralyzed state.

Dr. Chapin thought that a neuritis would occasionally explain cases which could not be accounted for on the supposition of a spinal lesion, and he would rather say halt! to the universal spinal cause of disease. With regard to pain, it was difficult to locate it along a particular nerve in children, but in his cases it was acute and persistent, and not due simply to stretching of tendons.

The Treatment of Acne.

Dr. John Kent Spender thus writes in the *Lancet* (January 8):

In order to promote a healthy action of the sebaceous glands, and to prevent the formation of what are called "comedones," the following plan should be adopted, as originally described by Dr. Liveing. The steps of his method are as follows: (*a*) Steam the face every night by holding it over a basin of hot water for a few minutes. (*b*) Rub the skin for five or ten minutes with soap (I prefer terebene soap) and flannel, or with a soft nail-brush; then sponge off the soap with warm water. (*c*) When the face has been dried, a lotion should be applied, composed as follows: Half an ounce of precipitated sulphur, two drachms of glycerine, one ounce of spirits of wine, with three ounces each of rose-water and lime-water. This is allowed to dry on the skin and remain on all night. In the morning the face is cleansed with warm oatmeal and water or weak gruel. If, for any reason, an ointment seems preferable to a lotion, a combination of precipitated sulphur and vaseline is very useful. The treatment must be modified or suspended for two or three nights if the skin becomes sensitive and somewhat tender. Dr. Liveing contends that the most common cause of failure is want of perseverance or timidity on the part of the patient or of the doctor; and that we ought not to be frightened from continuing efficacious remedies by a temporary increase in the redness and irritability of the skin.* If, by any chance, this plan be unsuccessful, nothing is so effective as the application of potash soap in the form of a lotion. The lotion is composed of one ounce of soft soap, one ounce of rectified spirits of wine, and seven ounces of rose (or distilled) water. This should be rubbed in vigorously with a piece of flannel for a short time,

*The Lancet, January 19, 1878.

taking care not to make the skin sore. According to Dr. Liveing, the worst cases of acne will yield to the soft soap treatment if practiced with necessary caution.

For eight years and more I have followed in its main outlines Dr. Liveing's plan, and with great success. But the experience which only actual work brings has led me to make modifications to suit the various susceptibilities and irritabilities of human nerves and skin. Some of these modifications I will now relate in the fewest words. In the first place, something is often required to be done during the daytime to pacify the heat and throbbing, which are part of the usual history of acne. An excellent lotion, the heritage of nearly every dermatologist, is made by combining oxide of zinc, calamine, prepared chalk, lead lotion, and lime water, to which may be added a small quantity of glycerine. Let the bottle containing this be gently waved about so as to diffuse the materials, which are only held in suspension; then pour a little into a saucer, and with a sponge (reserved for the purpose), sprinkle the face from time to time. Wipe off, when necessary, with a bit of fine muslin, the powder which remains on the skin after the evaporation of the fluid, and the face may be washed occasionally with a little starch gruel. In the second place, the cases are not a few in which it is better not to use any kind of soap as part of the evening ceremonial. After the face has been steamed, we may put on a medicated jelly composed of oxide of zinc, gelatine, and glycerine. It must be liquefied by putting the vessel that holds it into hot water, and then applied with a brush. Then, thirdly, there are some sensitive skins intolerant of sulphur in any guise. When this is so, we should think of combinations of lead, and chalk, and zinc, blended as a quasi-ointment with the finest vaseline. There are several pharmaceutists in London and the provinces who prepare oleate of lead and oleate of bismuth; and Dr. McCall Anderson's formula of oleate of bismuth with vaseline and white wax has been aptly described as "one of the most healing of salves." Sometimes nothing agrees better than the old-fashioned but capital substance called Kirkland's "neutral cerate," which is composed essentially of lead plaster and olive oil. Whatever combination may be chosen (and only a ripe experience with a sound judgment can decide), the ointment should be smeared all over the affected parts of the face immediately after the process of steaming, and allowed to remain during the whole night. For the acne, which is often a trouble to young women at the time of commencing menstruation, I prescribe the following ointment with much confidence: Ammoniated mercury, a scruple; precipitated sulphur, a drachm; oil of the sweet almond, half an ounce; and white vaseline to make two ounces. By methods such as the above, industriously carried out, an ugly, blotchy face may be commonly restored to a fair share of comeliness.

In the treatment of acne there is still room for those emollient "dusting powders" which once occupied an important place in the therapeutics of the skin. Equal quantities of oleate of zinc and pulverized starch, with a small percentage of precipitated sulphur, may be put on several times a day after moistening the surface with a warm, damp sponge. Now and then a quiet acne may disappear entirely in a few weeks without any other application. But the extreme forms of the so-called acne rosacea require a whole battery of new remedial forces, as it seldom yields to mild and coaxing means. I refer with much satisfaction to a paper published in the early part of 1885 by Mr. Tom Robinson. He advises no parley with an enemy which cannot be tamed or dislodged after inflammatory hyperplasia of connective tissue has once been set up. When inflamed papules are developed, a lotion should be applied occasionally, composed of bisulphuret of mercury and almond emulsion (two grains of the former to one ounce of the latter). When the congestive process goes on to suppuration the face may be fomented with hot water; and after the acute stage has subsided, a combination of a scruple of yellow oxide of mercury and one ounce of lard ought to be rubbed into the face, and continued every night so long as it may seem necessary. Mr. Robinson's favorite means for tranquillizing an angry skin is a lotion composed of bismuth and glycerine of starch, lessening the starch by three-fourths.

It is time to say a few words about internal remedies. It is a pity that so much attention must be given to the diet and the details of cooking, as this is the real impediment in many instances to the attainment of even a moderate success. All food which is difficult to digest must be avoided, as the waste stuff which it contains is a source of physiological irritation and worry. Simplicity will best suit that "conscience of the body" called the stomach; and regularity in the meals is of high importance. Alcohol and tobacco are usually superfluous, and sometimes poisonous; but concerning the former an exception may be made in the

case of strumous young men and women, to whom a little beer (taken with meals) is often quite valuable. I must insist upon the daily constitutional walk as a necessary article of faith and practice; and I venture to add that systematic writers on diseases of the skin do not lay sufficient stress on the proper ventilation of houses and rooms (especially the bed-room) as essential to the respiratory function of the skin. This function is thwarted and blocked when the surrounding air is deficient in quantity and chemically bad in its quality; and we cannot wonder at the prevalence of acne and other similar skin diseases, when we call to mind the polluted elements which some people love to breathe.

With regard to the Pharmacopœia, the rule is almost absolute that arsenic is nearly the last drug which a practitioner should think of. Combined with perchloride of mercury, arsenic has a useful place in the management of dull inert acne in plethoric persons. Iron is often necessary, and can be conveniently given in one of two forms—either (*a*) as the ammonio-citrate, with an effervescing draught of citric acid and bicarbonate of potash; or (*b*) as the sulphate of iron, with dilute sulphuric acid and sulphate of magnesia. The mild aperient action of the latter combination is a distinct help; and further aid in this direction is afforded by the pill of aloes and myrrh.

Ethyl Bromide in Ophthalmic Surgery.

Dr. S. Latimer Phillips thus writes in the *New Orleans M. and S. Jour.:*

In ethyl bromide we have a most thorough, safe, and efficient anæsthetic when the state of anæsthesia is to be of short duration, and in the hands of a surgeon who is familiar with its administration.

It is peculiarly well adapted to the practice of ophthalmic surgery, where the bulk of operations are painful, but of short duration. Then its effects are so evanescent, and as a rule its administration is followed by no unpleasant symptoms which so often follow in the tracks of chloroform and ether; such as headache, nausea, vomiting, excitement, etc.

To one who has never seen this anæsthetic used, it is indeed surprising and pleasing in the extreme, to see how easily the patient is brought under its influence, the operation performed, and in a few minutes the patient restored entirely to consciousness, and able immediately to go about his business, unaware, but for being told, or the soreness consequent upon the wound made, that an operation has been performed; which otherwise than with an anæsthetic would have been most painful.

It is hard for me to understand how any thing so beautiful and marvelous in its effects should be so neglected by the profession in general. It is true, death has been caused by its use, and all are more or less familiar with the cases reported by Drs. J. Marion Sims and Levis; the latter, one of its earliest advocates. In Dr. Sims' case the operation was an extended one—and it certainly is not well adapted for such—Battey's operation for the removal of the ovaries. The patient was kept under the anæsthetic for an hour and a half; she came from under its influence, but shortly died with symptoms of bromide poisoning. After death the tissues were permeated with the odor of the latter drug. Chemical analysis of a sample of the preparation used in this case was made, and it was found to be impure. Dr. Levis' case—vesical calculus—was far gone in phthisis pulmonalis, a case, which, under ordinary circumstances, ought to have prohibited the use of any kind of anæsthetic.

I have used it hundreds of times in ophthalmic surgery, and have seen it used as many more, and as yet have to see my first case of trouble due to the ethyl.

In all these cases the anæsthesia was of short duration, and in the majority only one administration was required at the same sitting. In some of the more lengthy operations where the inhalation had to be repeated, I have seen vomiting follow, but where only one was required I cannot call to mind a single case of this.

When ethyl bromide is given by inhalation there is at first a short stage of excitement; the pulse quickens; the respiration increases in frequency; pupils are semidilated, conjunctivæ congested, as are face and ears, which remain so throughout the anæsthesia, as long as there is no danger. After a few strong inhalations have been taken the muscles relax; the reflexes are abolished, as is shown by touching the cornea, without spasmodic contraction of the orbicularis muscle following. The patient is now ready for operation, and one has to be quick, for this stage only lasts for half a minute or so in most cases.

The means I employ in the administration are these: A towel is folded in the shape of a cone, made to fit nicely over the nose and mouth, having previously laid a piece of thick paper between the folds of the towel to prevent any escape of vapor. The cone can be

held in shape by one of the large pins generally worn by ladies to keep the bonnet secure, the point turned towards the apex of the cone to prevent it sticking the patient if the towel should be unduly pressed over the nose and face. It would be well at this point, in case the patient is an adult or child old enough to understand, to explain to them that the impression will be a choking one, but that they will not choke, and instead of struggling to get free, they must try and blow the napkin from the face, for making such forced expirations they are bound to take an inspiration, and soon get a goodly supply of the vapor. Children will cry; this is all the better—they will soon take in enough to be anæsthetized. A half to a drachm and a half will be poured into the apex of the cone, and the latter applied over nose and mouth tightly. A few deep inspirations, and the patient is gone.

Some patients will have stertorous breathing and foam at the mouth; this means, as a rule, that they are pretty well under its influence, but need not frighten one. In young children inhaling ethyl bromide, there will often be a relaxation of the sphincters, and an evacuation of fæces or urine. This can be provided for by having at hand a rubber blanket to put under the child and protect the couch. With this anæsthetic all operations that take only a short time can be done; such as slitting puncta, probing lachrymal duct, removal of tarsal tumors, optico-ciliary neurotomy, tenotomies of the recti muscles in children too young to bear the operation under cocaine, and adults too timid, and many other operations in ophthalmic as well as general surgery, which will readily be suggested to the mind of an apt surgeon.

I feel sure that any one after giving ethyl bromide a fair trial as an anæsthetic in all cases where the operation is to be one that will not take much time, and which, without artificial sleep would be too painful will agree with me that it is by far the most preferable known.

The Surgery of the Pancreas.

Dr. Senn, in the January number of the *American Journal of Medical Sciences*, concludes his exhaustive study of the surgery of the pancreas, based upon experiments and clinical researches. He formulates his conclusions as follows:

1. Restoration of the continuity of the pancreatic duct does not take place after complete section of the pancreas.

2. Complete extirpation of the pancreas is invariably followed by death, produced either by traumatism or gangrene of the duodenum.

3. Partial excision of the pancreas for injury or disease is a feasible and justifiable surgical procedure.

4. Complete obstruction of the pancreatic duct uncomplicated by pathological conditions of the parenchyma of the organ never results in the formation of a cyst.

5. In simple obstructson of the pancreatic duct, the pancreatic juice is removed by absorption.

6. General atrophy of the pancreas from nutritive or degenerative changes of the secreting structure is not incompatible with health.

7. Physiological detachment of any portion of the pancreas is invariably followed by progressive degeneration and atrophy of the glandular tissue.

8. Extravasation of fresh normal pancreatic juice into the peritoneal cavity, does not produce peritonitis, but is promptly removed by absorption.

9. Crushed or lacerated pancreatic tissue is removed by absorption, provided the site of operation remains aseptic.

10. Complete division of the pancreas by elastic constriction is never followed by restoration of interrupted anatomical continuities.

11. Limited detachment of the mesentery from the duodenum, as required in operations upon the pancreas, is not followed by gangrene of the bowel.

12. In all operations upon the head of the pancreas, the physiological connection of the peripheral portion of the gland should be maintained by preserving the integrity of the main pancreatic duct.

13. Partial excision of the splenic portion of the pancreas is indicated in cases of circumscribed abscess and malignant tumors, in all cases where the pathological product can be removed completely without danger of compromising pancreatic digestion or inflicting additional injury upon important adjacent organs.

14. Ligation of the pancreas at the point or points of section should precede extirpation as a prophylactic measure against troublesome hemorrhage and extravasation of pancreatic juice into the peritoneal cavity.

15. The formation of an external pancreatic fistula by abdominal section is indicated in the treatment of cysts, abscesses, gangrene, and hemorrhage of the pancreas due to local causes.

16. Abdominal section and lumbar drainage are indicated in cases of abscess or gangrene of the pancreas where it is found impossible to establish an anterior abdominal fistula.

17. Thorough drainage is indicated in cases of abscess and gangrene of the pancreas, with diffuse burrowing of pus in the retro-peritoneal space.

18. Removal of an impacted pancreatic calculus in the duodenal extremity of the duct of Wirsung, by taxis or incision and extraction, should be practiced in all cases where the common bile-duct is compressed or obstructed by the calculus, and death is threatened by cholæmia.

19. In such cases the principal source of danger, extravasation of bile into the peritoneal cavity, should be avoided by preliminary aspiration of the dilated bile-ducts, accurate closure of the visceral wound with fine silk sutures, and absolute physiological rest of the organs of digestion during the time required in the healing of the visceral wound.

A New Position for Ophthalmic Operations.

Dr. G. M. Giles thus writes in the *Brit. Med. Jour.:*

The supine position is, as most must have felt, by no means a convenient one for eye operations. It is, however, the only practicable one when chloroform is used as an anæsthetic. The discovery, however, of a local anæsthetic, in the shape of cocaine, leaves us free to adopt any position that may be found most convenient for patient and operator.

For the last fifteen months I have been employed with an exploring party in the regions lying beyond our North-West Indian frontier. Transport difficulties have rendered it necessary for us to fly very light. Hence, as may be well imagined, an operating couch formed no part of my equipment. A good deal of surgery of all sorts came to my hands, much of it ophthalmic, and I was often at a loss how to improvise a couch of some sort. Not unfrequently even the low country bedstead was unobtainable, so that one had to operate on the ground. Now, to operate even on a low bed is most difficult in ophthalmic cases, the surgeon's position being so constrained that all steadiness of hand is lost. Hence, after adopting cocaine, which I came to do very early in our travels, I began to try various positions with the view of finding one suitable to the peculiar exigencies of camp life, and finally hit upon the following position, which has been found so entirely convenient that I feel sure it is well worth a trial, not only by such as have to operate under difficulties, but even as a position of election:

The operator sits on an ordinary chair, with the knees well separated so that the patient may be able to sit on the ground between his feet. The position of the latter varies according to the nature of the operation and the side operated on. In ordinary cases, such as iridectomy, removal of pterygia, etc., he is seated with his back nearly to the operator, but with the face turned slightly to the left for the left eye, or to the right for the right. Seated thus, between the operator's feet, he throws back the head so that the occiput rests firmly on the surgeon's thigh; the left thigh in operations on the right eye, and *vice versa*. This position answers equally well for cataract extractions on the right side. For left cataract, however, unless the operator actually prefers to use the left hand, the following modification is necessary: Seated, as before, on the ground, between the operator's feet, he faces quite to the surgeon's left, then throwing back his head, and turning it slightly so that the chin points to the surgeon's hip-joint, he rests the occiput firmly on the operator's right knee. With the patient in this posture, it will be found perfectly easy to operate with the right hand.

The method is, no doubt, specially suited for dealing with Orientals, who are accustomed to sit on the ground; but for the limited time required for an operation, I do not think it will be found too constrained for Europeans. Primitive as it may seem, I feel sure that any one who will give it a fair trial will find the position much more convenient than either an ordinary operating-couch or a dental chair.

The Treatment of Stricture of the Rectum by Electrolysis.

Before an English medical society Mr. Whitmore read a paper on this subject, of which the following is an abstract: Ulceration was often a cause, but more often a result, of stricture; in many instances it was both a cause and an effect. Mr. Whitmore had treated incipient stricture, as well as old standing cases, with the best results by electrolysis. In one case he had dilated the rectum from the size of a No. 18 French rigid urethral bougie to that of a No. 9 rectal bougie in three months; no contraction had taken place during a clear fourth intercur-

rent month. In another case, that of a man who had undergone a severe operation for fistula nine years previously, and who had taken two years to dilate his rectum from No. 2 to No. 4 rectal bougie, and who was in a most crical condition from inflammatory symptoms, the author had increased the size from No. 4 to No. 7 in three months, no contraction happening in an intercurrent fourth month. Neither of the patients had been confined to bed, and much improvement had taken place in their health.

After some remarks from the President and Dr. Thudichum, Mr. Edwards said that he had tried electrolysis in two cases of stricture of the rectum, with some success. In cases of stricture of the urethra, of which he had treated upwards of forty by electrolysis, excellent results had so far followed, but sufficient time had scarcely yet elapsed for an opinion to be formed as to the permanence of the cure.

Mr. Harrison Cripps remarked upon the pathology of rectal stricture, and said that, of one hundred cases admitted into St. Bartholomew's Hospital, ninety-five were women and only five men. There seemed to be a close conneetion between child-bearing and the disease, the history generally being that the fourth confinement or so was a difficult one, and was followed by pelvic cellulitis; this caused the contraction of that portion of the pelvic fascia which runs round the rectum, whereby a "kink" in the gut was produced, which subsequently became the starting point of fibrous stricture.

Mr. Reeves agreed with Mr. Cripps in the main, but his view did not explain rectal stricture in single women. In the simple forms of the affection, he thought digital dilatation was the best treatment.

After some remarks by Mr. Benton, Dr. Althaus said he believed that these were the first cases in which electrolysis had been used in the treatment of stricture of the rectum. The effect of electrolysis was to cause some decomposition in the tissues; by this means subsequent contraction was prevented.

Mr. Whitmore replied, and laid emphasis upon the fact that his paper only dealt with fibrous strictures. With regard to the occurrence of stricture of the rectum in single women, it was certain that constipation was the chief cause.

—A thriving village of a thousand inhabitants in New Jersey is without a physician. The right kind of a professional man could at once secure an income of about $1500 a year. Particulars at this office.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The subject of sterility and the management of the secundines is treated in a reprint by Dr. William H. Wathen, professor in the Kentucky School of Medicine, Louisville.

——Dr. Nathan Allen, of Lowell, Mass., has published a thoughtful article on the relations between sanitary science and the medical profession.

——In a reprint before us, Dr. Julian J. Chisholm, of Baltimore, discusses the question whether in all cases rest should be recommended when the eyes are painful.

——Dr. C. H. Von Klein, of Dayton, Ohio, sends us a printed copy of a recent address by him, entitled "Rhinology in the Past and of the Future." It is an interesting resumé and forecast.

——Dr. Henry W. Stelwagon, of Philadelphia, has recently published some valuable clinical notes on the use of resorcin, ichthyol, and lanolin, in cutaneous diseases.

——A neat pamphlet has reached us containing two excellent papers relating to State medicine. One is by Dr. Isaac N. Kerlin on provision for idiotic and feeble-minded children; the other considers the duty of the State toward epileptics, and is by Dr. George H. Knight.

——A brief paper by Dr. Thomas Addis Emmet on certain mooted points in gynecology has appeared in pamphlet form.

——Two interesting surgical pamphlets have appeared from the pen of Dr. J. McF. Gaston, of Atlanta, Ga. One is on the surgical relations of the ilio-cecal region; the other on the surgical connections of that region, describing a new process for intestinal communication.

——In a pamphlet before us, Dr. W. H. Daly, of Pittsburgh, speaks first of laryngology, in America, and then of the simplest and most efficient treatment of diphtheria. The latter consists in the free administration of calomel and nutritious diet.

——A pamphlet of Dr. S. M. Cate, of Washington, D. C., bears the title "A Treatise on some Diseases of the Bones and Ligaments of the Spine." It is intended to advocate certain modifications of Sayre's procedures.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE MORTALITY OF ALCOHOLISTS.

An interesting debate concerning the death-rate of persons abusing alcohol occurred at the meeting of German Scientists and Physicians in Berlin (September 18th to 24th, 1886). Sanitary Counsellor Dr. Baer introduced the subject by remarking that the fact was well recognized that individuals frequently under the influence of alcoholic drinks, when taken sick, died sooner than persons of moderate habits, not considering at all diseases directly due to the action of alcohol. The well-known insurance statistics of John Scott show that of saloon-keepers between 24 and 40 years old 21 per 1,000 died, of other persons 10 per 1,000; between 40 and 60 years 60 per 1,000, while the general death-rate of the population at the same age amounted only to 35 per 1,000. Another statistical report, which compares the mortality rate of ministers with that of saloon-keepers (rather an antagonism?), bears this result:

	Ministers.	*Saloon-Keepers.*
Age, 25 to 35,	per 1,000, 4	per 1,000, 14.
Age, 35 to 45,	per 1,000, 6	per 1,000, 20.
Age, 45 to 55,	per 1,000, 13	per 1,000, 38.

In England the following figures are used as a basis for all calculations of probability with reference to life insurance: 14 per cent. of all deaths are indirectly due to alcohol; 4 per cent. are directly caused by alcohol. These figures demonstrate the undeniable fact that the whole mortality-rate of the United Kingdom would be 20 per cent. less were it not for the abuse of alcohol. These tables are of the more value as they have not been put together by fanatical temperance apostles, but by men who themselves did not object to the moderate use of spirituous drinks, but who well recognized the pernicious influence of the abuse of intoxicating beverages.

Privy Counsellor Dr. Spinola reported the mortality rate of the Berlin Charité Hospital with reference to death due to alcohol. From it we notice that the death-rate due to this cause has increased 36 per cent. Another fact, mentioned by the same observer, is also of interest. During the year 1880 exactly 300 persons were treated for delirium tremens; in the year 1885, on the other hand, 671 such persons were attended for the same complaint. He ascribes the enormous increase in the number of such patients to the cheap whisky that is now sold in Germany, and he advises a high license and high taxes as the best means to counteract this deleterious influence.

Prof. Alglave, of Paris, described the experiments which were recently made in Paris with a view of determining which kinds of alcohol, were the most deadly in their effects. These researches have proved that the higher alcohols, especially, however, the amyl alcohol, as obtained from potatoes and corn, were the most virulent in their action, while the ethyl-alcohols seemed far less poisonous.

As it will probably be forever futile to endeavor totally to suppress, if not the manufacture and traffic, at least the use of alcoholic beverages, but as all will agree that modern society should do something to diminish the enormous ravages and the immense misery caused by alcohol, we must try in some other way to limit its bad effects. From the foregoing it will be clear that the sale of unrectified spirits should not be permitted. Next, the use of fermented liquors should be encouraged and a very high duty be imposed upon the manufacture of all distilled spirits. Finally, a high license, the higher the greater the amount of distilled beverages sold, should further limit the sale and more confine it to men more scrupulous in this business. The sale of liquor, however, to persons already under the influence of alcohol, or to such as are known as habitual drunkards, or to individuals whose wives or friends have cautioned the saloon-keepers not to sell them any intoxicating drinks, should be punished severely, not only by withdrawal of the license, but also by very high fines and damages, to be collected not only from the saloon-keeper, but also from the owner of the premises in which the liquor is sold.

Teetotaler or not, all justly-minded will agree that the immense increase in the death rate caused by the abuse of alcoholic liquors should in some way or other be stemmed. It is time that a halt be called, or a few decades more and our citizens will become as degenerated as is now but too plainly apparent in the general population of France, where absinthe and other strong liquors have undermined the health of the individual and produced a debilitated offspring. Let all honest men drop all fanaticism, and make a united effort to limit the dangerous abuse.

THE MOST EFFECTUAL TREATMENT IN CHOLERA.

Before the medical profession had any idea that one day bacteriology would be added as an important branch to its various departments, and long ere the name of comma bacillus was ever known, experience had established the good result obtained from strongly astringent remedies in Asiatic cholera. This empirical treatment, whose great value was especially demonstrated in the last London epidemic, has at last found its scientific explanation by the researches of Cantani in Naples (*Deutsche Med. Zeit.*, December 14, 1886).

Cantani made a series of pure cultures of comma bacilli, and after having added the latter to various peptone solutions he added to these all possible drugs, from which he expected some unfavorable influence on the further development of the micro-organisms, the pathogenic cause of the Asiatic disease. When he had thus discovered the best means to kill the bacilli—means, however, which by themselves were not deleterious to the health of human beings—he employed the opportunity offered him by the epidemic of cholera then ravaging Italy to test the practical action of the remedies, thus theoretically determined. The results which he obtained, and which were acknowledged as correct by various well-known authorities at the meetings of the last Congress of German Scientists, were as follows:

Two indications had to be met with:

1. Limiting the further propagation and the development of the cholera bacilli already present in the intestinal canal; and,

2. Bringing about the rapid expulsion of the poison already imbibed.

For the first purpose the enteroklysis of a hot solution of tannic acid has proved by far the most successful. Experiments had previously demonstrated that at a temperature of 100° a solution of this drug of from one-half to one per cent. suffices, when applied to pure cultures of cholera-bacilli, to suppress their power of propagation and to make the microbes sterile without killing them. The elimination of the cholera-virus is also fostered by the hot enteroklysis of tannic acid; for though a few minutes after the injection some portion of the fluid is expelled, the larger part of it is retained and evinces its favorable action by the rapid re-establishment of the urinary secretion, whose cessation is one of the earliest phenomena of grave cases.

Observations have established the undeniable fact that by the enteroklysis the fluid does not penetrate only so far as the upper part of the duodenum, but that some of it also penetrates to the stomach, where it seems to be remarkably well borne. The bowels become dilated under the influence of these injections, and an anti-peristaltic motion is produced.

To stimulate the excretion of the virus already absorbed, there is only one method that resulted in success, viz., the hypodermoklysis of warm water. Though, as C. first hoped, the danger is not at once removed in all cases, he succeeded in reducing the mortality two-thirds, so that in the very worst cases the death-rate amounted but to 40 per cent. against 60 per cent. of those recovering.

The effect which at once sets in after the hypodermoklysis of warm water is surprising indeed. Individuals who were lying on their beds cold and unconscious, began a few minutes after the injection to give signs of returning appetite, and to micturate. The injection, however, should not be made in the neck, but on one side of the abdomen, and best there near the ileo-cæcal valve.

C. obtained one more practical result from his interesting and important observations. He found that a solution of tannic acid of 1.40, when daily used twice as a clysma, acted as the best preventive against cholera. He made all persons, with whom he was acquainted, drink occasionally a mouthful of a still weaker solution, and advised them to make daily use of the injections. Though some of these individuals lived in the midst of communities stricken with the epidemic, but very few showed any signs of the disease, and these were so mild as at once to yield to the method above described. These experiments were made while the cholera was at its height in Italy, and their value is therefore the greater.

Though it is very problematical at present that the Asiatic disease will visit our shores in the near future, especially if the United States government does its whole duty in the enforcement of proper sanitary measures, it may be well to make a note of C.'s treatment, and to try it in case of an outbreak of cholera when a better method is wanting.

Notes and Comments.

Dislocation of the Humerus Reduced by Right-angle Traction.

"In his memorandum on the above subject in the *Brit. Med. Jour.* of November 6," says Dr. E. H. Lloyd, "Fleet-Surgeon W. Digby Longfield speaks of 'steadying the shoulder with his left hand.' Now, as I think that the acromion has not hitherto been sufficiently made use of as a point at which the scapula may be fixed and counter-extension be advantageously applied, I venture to bring forward, without claiming any merit of priority, a 'variety' of the right-angle traction method of reduction which I first tried in 1859, when house-surgeon at the London Hospital, and have used since then in my army practice. It is briefly as follows: The patient being seated, the surgeon stands by his side, places the palm of his right hand above the inner condyle of the humerus, grasps the arm, and raises it to a right-angle with the patient's trunk; he grips the patient's wrist firmly between his own arm and right side. Then having placed the upper margin of his left palm on the prominent acromion, he makes steady traction on the arm to disengage the head of the humerus from its abnormal position, at the same time making counter-pressure on the acromion in a direction inwards and somewhat downwards; the head of the bone is then lifted into the glenoid cavity by making use of the patient's arm as a lever of the third kind, the fulcrum being at the wrist, firmly fixed to the side of the operator.

"The force required for reduction by the right-angle methods is, as stated by Dr. Macleod and Fleet-Surgeon Longfield, comparatively small; but, with the hand on the acromion, considerable traction-power can be used, if necessary; the surgeon's knee, too, may be placed against the axillary border of the scapula.

"It is time that the old heel-in-axilla method should be altogether discarded; it cannot but tend to produce still further laceration of ligaments and muscular fibres."

Treatment of Chronic Ulcers.

Dr. A. S. Reynolds recommends (*Med. News*, Oct. 9, 1886,) the sub-iodide of bismuth as a dressing for ulcers. He has found that "it controls inflammation, allays irritation, suppresses suppuration, promotes granulation, and induces cicatrization." It is bland and unirritating, and may be used on any surface. He regards it as almost a specific for acute and chronic ulcers. Its action is assisted by the removal of pathological elements which would retard or impair healthy tissue formation. Before using it he supports the varicose veins in a varicose ulcer; destroys the new growth in a lupoid or epitheliomatous ulcer; applies chloral to an irritable ulcer, and a five per cent. salicylic acid powder to a readily bleeding ulcer; resolves exuberant granulations with bromide of potassium; cuts down callous edges with salicylic acid or the knife, and stimulates atonic syphilitic ulcers with

nascent iodide of mercury. In the majority of cases the sub-iodide of bismuth alone will be sufficient.

In applying the dressing, the surface of the ulcer is first to be washed and thoroughly cleansed, disinfected, and then dried. The powder is dusted over all, either alone or in combination with any other powder, such as calomel, salicylic acid, or bromide of potassium. The limb is then strapped with adhesive plaster for an inch above and below the swollen or inflamed part. Over all a firm bandage is applied. The dressing is changed in from one to four days. When the ulcer looks healthy, dress the granulations with the sub-iodide, protect with a Maltese cross or perforated square of plaster, cover with a thin layer of absorbent cotton, and again apply the bandage.

Action of Drugs in Albuminuria.

An interesting communication on this subject was read in the Section of Therapeutics at the Brighton meeting of the British Medical Association, by Dr. Robert Saundby. He pointed out the difficulty of foretelling what action drugs might possess on the renal processes in genuine albuminuria. The number of drugs with which he experimented was very large. The following are his chief conclusions: Alkalies used in the form of diluents, such as a quart of bitartrate of potash imperial (one ounce and a half to a pint) daily, gave distinctly favorable results in cases of chronic persistent and copious albuminuria. He has employed also citrate of lithia, bicarbonate of potash, ammonic benzoate, and bicarbonate of soda, and includes them in the favorable opinion. The beneficial effect was not due to the formation of alkali albumen; for Esbach's fluid, which was the method employed, precipitates that form of albumen. Tannate of soda, or rather an ounce mixture of tannic acid and bicarbonate of soda, of each ten grains, with fifteen minims of glycerine, also gave good results. In one case the albuminuria was diminished nearly one-half. Nitroglycerine and fuchsin appeared to have no good effect. Digitalis and other heart tonics — caffeine, strophanthus, sulphate of sparteine, iron salts, acetate, and perchloride—increase the amount of albumen passed. Apocynum was not found to have any diuretic action in drachm doses of the tincture, and it increased the albumen in two cases. Turpentine had no beneficial effect, though hæmaturia followed its employment in one-minim doses. Doses of the $\frac{1}{1000}$ of a grain of bichloride of mercury were also inoperative.

The Removal of the Ovaries in Hysteria.

After meeting with considerable opposition in Paris when first made known, Battey's operation is gradually coming into favor, and a number of speakers were able to give their experience of the operation at a recent discussion at the Société de Chirurgie. M. Terrier mentioned the case of a woman who, manifestly hysterical, suffered from intolerable pains in the ovaries at the menstrual periods. No relief being obtained by ordinary means, and life being a misery, these organs were removed last February. The right ovary caused no difficulty, but the left was so bound down by adhesions that it could only be extracted piecemeal. Since the operation there has been but insignificant malaise at the catamenial periods, which are perfectly normal. The hysterical condition, although it remains, appears amended; there are no longer any abdominal pains, and the general health is good. This is the second success of the kind obtained by M. Terrier. M. Lucas-Championnière has also performed the operation in two cases: one of his patients died three days after the operation; the other was relieved of her symptoms, and at the same time cured of bad temper. Before the operation she easily became angry at trifles, whereas she is now quite calm. M. Monod said that he also had been successful in two instances, and M. Pozzi was able to endorse the treatment by one operation.

Subcoracoid Dislocation of Shoulder Reduced by Right-angle Traction.

J. G., aged 85, sustained a dislocation of the right shoulder, the head of the humerus resting under the coracoid process. Dr. James H. Parkinson (*Brit. Med. Jour.*) directed the mattress on which he rested to be placed on the floor; and, fearing that his weight (about 115 pounds) would not be sufficient to act as counter-extension, he passed a roller-towel round the thorax, giving the end to an assistant, desiring him to "hold against" him. Grasping the arm above the wrist, he made steady traction, at the same time gradually raising it from the side; when at a right-angle from the body, he ceased to elevate, but maintained the traction, and in less than five seconds the bone went into place with a faintly audible snap. When the arm was raised, the discomfort lessened, and the patient bore the manipulation with less complaint. He sub-

stituted the towel for counter-pressure by the foot, as he was uncertain of the elasticity of his ribs. He had on former occasions reduced dislocations in the same manner, but unintentionally—that is to say, he was endeavoring to carry out White's method, or one of its modifications—and he presumed many others have had similar experiences.

Spinal Hemorrhage.

Before an English medical society, Mr. W. H. Maling exhibited a man who had recovered from a severe injury to his spine. Six months before he had fallen from a scaffolding about twenty feet and struck his back, about the lumbar region, on some iron bars. He was admitted into the infirmary semi-conscious, and with complete loss of power in the lower extremities. His water had to be drawn off, and he had no power over the act of defæcation. Sensation was not impaired. A month after admission he had a smart attack of pneumonia, and, in spite of every care, a large bed-sore formed over the sacrum. Six weeks after admission he could move the toes of the right foot. Galvanism was used daily, and the muscular power in his legs gradually increased until ten weeks after admission, when he could raise both legs from the bed. It was not till thirteen weeks from the accident that he regained perfect control over the sphincter ani. On being discharged, four months after admission, he was quite well, with the exception of the bladder weakness, for which he was still obliged to use a catheter twice daily. The case was diagnosed as intra-medullary hemorrhage, involving mainly the anterior part of the cord.

Pomegranate Root in Intestinal Affections.

Dr. Edward Nicholson, in a paper read before the Liverpool Medical Institution (*Practitioner*), calls attention to some little-known properties of pomegranate root. His experience with it has been mostly with young children in India. He found that whenever a young child lost its appetite, had more or less irregular bowels and a somewhat tumid belly, was peevish by day and restless at night, when it was wasting, and the symptoms were negative as to worms or fevers, decoction of pomegranate root invariably effected a cure. The symptoms were mostly found in children about two years of age, but might occur at any time up to seven years. No particular dietary was found necessary. He has since found the drug equally efficacious in similar conditions in children in England. He has usually given the decoction in ounce doses, three times a day, and has never seen any toxic effects from its use. In certain obscure diseases in adults, where there was cachexia with evidence of abdominal disturbance, he has also found the pomegranate root serviceable.

Poisoning by Cocaine.

Before a British Medical Society, Mr. Kelham related this case. A man aged thirty took 4½ grs. of hydrochlorate of cocaine in solution by mistake. In twenty minutes he was seized with severe pain in the stomach, throbbing of heart, loss of eyesight and of power in the legs, with incoherence of speech and confusion of ideas; no unconsciousness. Severe vomiting came on, with cramps in the stomach and legs, very profuse perspiration, intermittent action of the heart, cyanosis of the face, and feeling of suffocation; then severe prostration, shivering, and coldness of the skin. The severe symptoms passed off in about three hours, but the prostration and vomiting lasted all next day. Thirty-six hours after taking the cocaine he began to lose taste, and had a leathery feeling in the mouth and tingling of the fingers. The treatment consisted in emetics and stimulants.

Toxic Effects of One One-Hundredth of a Grain of Sulphate of Duboisin.

Dr. Chadwick, of England, relates in the *Lancet* a case where this amount of the drug, instilled for examination of a senile cataract, produced a state of delirium lasting many hours, leaving the patient totally unconscious of what had occurred. There was great muscular weakness, and many strange actions were performed. It was suggested that the susceptibility to this drug reached its maximum in old age, and that the similarity between the symptoms and those of senile atrophy, popularly known as "softening of the brain," might suggest that its action was by causing spasm of the cerebral arterioles, and might indicate a possible liability to that form of pathological change.

Absorption of Corrosive Sublimate by the Skin.

Dr. Kopff states in the *Prezglad Lekarski* that, having made seven experiments with careful analyses according to the methods of Schneider, Schridde, and Lehmann, with the

view of determining the power of absorption possessed by the skin for corrosive sublimate, he has found that healthy skin can absorb small quantities from aqueous solutions containing from 1 to 2 per cent. of the salt. The quantity absorbed, which, however, is never large, seems to depend mainly on the degree of concentration of the solution. The chloride of mercury is also invariably excreted very soon after it has been absorbed.

Neuroses at the Menopause.

Dr. William Goodell tells us that it not infrequently happens that we find women who are passing through the menopause complaining of a burning pain in the abdomen, running down through one iliac region to the vulva. To such women he gives:

℞. Ammonii chloridi, ℥ij.
Ammonii bromidi, ℥iv.
Tinct. gentianæ co.,
Aquæ, āā f℥iij. M.
Sig.—A tablespoonful, in water, before each meal.

or,

℞. Acidi arseniosi, gr. $\frac{1}{40}$.
Ferri sulph. exsiccati,
Extract. sumbulli, āā. gr. j.
Assafœtidæ, gr. ij. M.
Ft. pil. j.
Sig.—One after each meal. If this does not have the desired effect, the dose may be increased.

A New Hypnotic.

Dr. Ghillany, pharmacologist to the Vienna General Hospital, has succeeded in preparing an alcoholic extract from the roots of Piper methysticum (kava-kava), which is called "extractum kava depuratum." Experiments made with this drug by some physicians of the hospital proved it to be a valuable hypnotic. In all the cases where it was administered sleep was produced, without any disagreeable consequence; even headache, following generally the exhibition of hypnotics, did not occur. It was given, as a powder, from 2 to 5 centigrammes being a dose; or as a suppository containing 2 centigrammes.

As Good as a Hypodermic.

The *Medical World* says that if you want as sure and speedy action from your drugs as if you gave them hypodermically, administer them in hot water. One-half the dose will have the effect. The reason is obvious. If the dose be given in hot water it is quickly absorbed, and the force of the drug thrown upon the system at once. Few people realize how long the dose will remain in the stomach if that viscus be chilled. Beaumont found that a glass of ice-water stopped digestion for one hour. This method of administration is particularly suitable for the vegetable preparations, opiates, etc.

Milk as a Prophylactic against Renal Albuminuria in Patients with Scarlatina.

Musatti has combined milk diet and cold baths in scarlatina, with the best results both in mitigating the severity of the fever and in preventing the nephritis which so often occurs. He employs milk from the beginning of the disease, and he has not seen the evil effects of cold bathing in causing renal congestion and irritation, of which others have spoken. With due care against shock and collapse, he would repeat the cold application every two hours if needed. Jaccoud is quoted as supporting the author's use of milk.

Surgical Dressings.

In the clinical wards of Professor Albert, of Vienna, experiments are made now with fossil meal (Kiesselguhr) as a surgical dressing. The fossil meal is sterilized and mixed with the antiseptic solutions of carbolic acid, sublimate, etc. The cavities of the wounds are stuffed with the paste prepared in this way. The results obtained with this dressing are very good; healing seems to be very much promoted by the mechanical action of the minute particles of the meal.

Ligature of the Funis.

To the Obstetrical Society of Boston Dr. Hodgdon spoke of an accident, quite unique in his experience, that had recently occurred to him. In tying the funis with a piece of twine he had completely cut it through, and the blood spurted freely. In answer to a question, he said he had frequently cut the funis, without tying it, after pulsation had ceased, and had never known the funis to bleed; but he never dared to leave the house without having applied a ligature.

Large Thrombus of Right Labium.

Dr. W. M. Jones reported to an English society this case, which he was called to see about six hours after labor in a young primipara. He opened it, and evacuated more than a pint of clot, and applied carbolic dressings and pressure. Severe eclampsia and suppression of urine followed, but the woman made a good recovery. There was slight suppuration, but in a fortnight's

time the wound had quite healed, leaving the parts in a normal state.

Treatment of Anal Fissure.

Dr. Crequy (*Les Nouveaux Remedes*, November 24, 1886), proposes to treat this affection by introducing within the fissure a fragment of lint soaked in a solution of chloral, 1 to 50. This application is made after the morning stool, and is expelled on the following day, when the bowels move. Its action as a stimulant to granulations and a local antiseptic has been most happy.

Cocaine in Labor.

Dr. Hertzhorne recommends (*Lancet*) the use of a compound of six parts of cocaine, twenty-four of vaseline, and twenty of glycerine, to be applied to the parturient canal during the second stage of labor for the purpose of producing anæsthesia of the parts, and so vastly lessening the pain incident to that stage.

Resorcin in Eczema.

Dr. Chace (*Therapeutic Gaz.*, Nov. 15, 1886,) reports prompt and complete cures of eight cases of chronic eczema from the use of the following:

℞. Resorcin, ℥ij.
Glycerin, q. s. ad. ℥ij.
Sig.—Apply with camel's hair pencil morning and evening.

Correspondence.

Suicide by "Rough on Rats."

Eds. Med. and Surg. Reporter:

An interesting case came under my care during the past week which, through the verdict of the coroner's jury, has become a subject of public discussion, and its history may be of some service to practitioners in general.

On the night of January 18, 1:30 a. m., a man called me to see a niece of his, twenty-one years of age, who he thought had taken poison. I arrived at the house about 1:40 a. m. Found patient sitting on chair complaining of nausea; pulse 80, full and strong; respirations nineteen per minute; temperature normal; skin moist; tongue and throat normal; *no absolute pain;* no purging; no special soreness nor any pain on palpation of abdomen; pupils slightly dilated; lips and facial expression quite natural. Could get no distinct history from patient of having taken any poison, as her answers to questions were unintelligible and unreliable. From family gained following history: Had been melancholy for some time; uncle had reprimanded her sharply for some neglect of household duties; she went out of house at 8:15 p. m., soon returning. About 11 p. m., went down stairs and asked for some gin and peppermint. At once began to vomit, and so continued, with intermissions, until I saw her. Found she had vomited in her room previous to going down stairs. Could not find any evidence of poison about. Complained more of nausea than pain. I placed her upon a lounge, and from time to time examined her general condition. Gained no new information. Nausea ceased somewhat, and she dozed quietly, having no pain, except a soreness from retching. Examined vomit (about three quarts), and gained no information. No odor; no peculiarities. Ordered milk, but had none; infusion slippery elm, but had none; hot coffee.

Remained until 2:35 a. m., giving occasional draughts of coffee, the most of which she vomited. When I left she was resting quietly, and said she felt much better. Told family I saw nothing serious in the case from her symptoms, and suggested an idea that perhaps some druggist had given her a nauseant emetic as a ruse.

Furthermore, at this time, five hours after ingestion of poison, and after such profuse vomiting, absorption had taken place, the stomach was empty, and as the ferric antidote was only of use before absorption to form an insoluble compound, there was nothing left for me to do but treat the case on general principles. I therefore left a prescription:

℞. Spirits am. aromat., gtts. xx.
Sol. cocaine (4 per c.), f. ℥j. M.
Sig.—Tablespoonful, repeated in one hour, if necessary.

I told them if she should complain of pain in stomach to get prescription filled and give according to directions. I then left for home.

Morning, 8:30 a. m., patient died. I then gained the following history: After I had left (2:35 a. m.), uncle remained with her until 4 a. m., and having rested so well, they had not gotten prescription filled. She walked upstairs to water-closet, and fifteen or twenty minutes later returned; sat on chair awhile, and then complained of some pain and dizziness. Laid down on lounge. Family then went on with household work; one lady washing clothes near, to whom patient made

no complaints, but said she felt better. At 8:30 a. m. they went to remove her from lounge to next room, and found her dead.

The case was at once reported to coroner, and investigations at once begun to discover the poison. Found "Rough on Rats" box in yard. Druggist was found who sold her the powder, 8:15 p. m., night previous.

Post-mortem three and a half hours after death by coroner, found stomach intensely inflamed, and mucous membrane brownish-red, and swollen; contained a pint of dark fluid. This fluid, analyzed by a chemist, was found to contain traces of arsenic, but no phosphorus; no heart lesion; no further examination of organs or body.

Evidence showed she had taken poison before 9 p. m., and about five hours previous to my being called, and had vomited freely before she first complained to family.

Jury returned verdict of death from "Rough on Rats," and added that "they believe more could have been done than was done toward the recovery of patient."

Although they are all laymen, and the one who insisted on the latter clause is a most ignorant man, yet I have been compelled to stand a greater share of censure than the family, who seemed to me to take but little interest in the welfare of the patient, who was an orphan and a late immigrant from Germany.

I cannot conceive how such active toxic gastritis could have existed at the time I saw patient, and she not complain of intense pain; and I am fully convinced that her visit to the water-closet was for the purpose of taking more poison, as she seemed determined in her idea of suicide.

Did the jury do right? The newspapers all condemn their action.

T. F. Heebner, M. D.

Scranton, Pa., Jan. 22, 1887.

A Remarkable Case of Congenital Hydrocephalus.

Eds. Med. and Surg. Reporter:

On July 16, 1886, I attended Mrs. B——, in her first confinement. The labor was somewhat tedious, and the woman becoming exhausted, I found it necessary to use the forceps. The child's head being abnormally large, was delivered with some difficulty. The child was a female, and was well-formed, except the hydrocephalic head. The mother made a good recovery. The child was strong and took nourishment well, but its head increased in size rapidly. The child lived four and a half months. At the time of its death, its head measured twenty-nine (29) inches in circumference. That it might be more readily placed in a coffin, I tapped the head and drew off five pints of liquid.

Roxborough, Pa. W. C. Todd, M. D.

Cocoa Butter for the Nails.

Eds. Med. and Surg. Reporter:

In the Med. and Surg. Reporter of January 15, 1887, p. 91, is a quotation from the *Therapeutic Gazette* of a statement of Thomas H. Irquhart on "Tin Oleate for the Nails." For finger nails that form longitudinal ridges, or that become fragile, split and break, I have used theobroma oil (cocoa butter) with most satisfactory results. The hands and nails are warmed, the butter in small quantities rubbed on the palms and with these upon the nails at intervals of two or four days. Two applications sometimes suffice for a month or more, the nails becoming very tough and glossy, and the ridges disappearing in a very short time.

Agricultural College, Miss.

Forceps in Labor.

Eds. Med. and Surg. Reporter:

In recent numbers of the Reporter appear letters from Wm. F. Mitchell, M. D., on "Midwifery in the Country." In the first one he says, "I have had something over six hundred cases of labor since I am in practice." In all of these cases he has never used the forceps. He hardly knows whether "to be proud or ashamed to say I have never used this instrument." In the Reporter for '81 I had an article strongly advocating the frequent use of this instrument, and looking back through an experience of over thirty-six years of active practice, I emphatically reiterate what I then stated—The longer I practice medicine the more firmly established is my opinion of its inestimable value and the oftener I resort to its use.

Dr. M. prides himself that he has "never had a case of lacerated perineum." In my frequent use of the forceps I have had just one, which healed so perfectly with no operation that the woman gave birth to a child in eleven months after. Now Dr. M., I presume, will hardly claim that the forceps should *never* be used; in fact he acknowledges "that," in looking back, "I can see those instances in which the life of the child might have been saved by the use of the forceps," and yet he allows himself to go "some miles in the country" to attend a case of midwifery,

without carrying his forceps so that when the "*necessity* (italic mine) *did* (italic his) arise I would have none with me" and says this might be unfortunate perhaps for him. I would be glad to hear if the woman thinks it was in any way unfortunate for her. He acknowledges that he has "had a good many still-born children." I should think more than likely. His remedy in lingering protracted cases of child-birth is for the physician "to possess his soul in patience."

This reminds me of old Spraken's (of Spraken's Basin in the Mohawk Valley) remedy for fogs. A guest one morning on rising found the country covered with a dense fog. Mr. Spraker assured him that he had a remedy that would surely dissipate the annoyance. On the gentleman inquiring what it was, the old gentleman said they would go in and take a good drink of whisky, and that would drive away the fog. Suiting the action to the word, they went in and imbibed. Bye and bye, the stranger observing the fog had not lifted any, Spraker said they must take another drink. Asking how many drinks it took to clear up a fog, Mr. Spraker said about a week ago it took twenty, but that was a very foggy morning.

I wish physicians who are so ready to possess their souls in patience in such cases could change places with their patients for a while, and see how long their patience would prove a "welcome guest." How any physician of ordinary skill can spend hour after hour (to the neglect of other patients), by the bedside of a woman in the unutterable agony of a tedious labor, withstand her tearful pleadings "to do something" for her, and yet withhold relief when it can be so easily, so quickly, and so *safely* furnished by the skillful, judicious use of the forceps, is a mystery.

T. C. Wallace, M. D.

Cambridge, N. Y.

News and Miscellany.

The Archæology of Artificial Limbs.

The *Lancet* says that the history of medicine is all but silent on orthopædic surgery. And yet the Greeks and Romans, who, as archæology has shown, had anticipated much of modern dentistry, cannot have been without artificial substitutes for limbs lost in the vicissitudes of peace or war. Herodotus tells us of a captive who amputated his foot to free himself from the shackle, and thus escaped to his friends, who replaced the limb by a wooden one. The elder Pliny (Nat. Hist., vii., 28, ed. Mayhoff) records the case of M. Sergius, great-grandfather of Catiline, who lost his right hand in his second campaign, was wounded twenty-three times in two campaigns, and thus had the complete use of neither hand nor foot. Twice made prisoner by Hannibal, he twice escaped, after twenty months spent in chains. He fought four battles with his left hand only, and then made himself a hand of iron, which he fastened on to fight with, and, thus accoutred, raised the siege of Cremona, protected Placentia, and took twelve camps of the enemy in Gaul. Similar substitution for amputated arms or legs must have been in use even before the time of Sergius; so at least we may infer from the treasure-trove turned up at Capua in 1885, in a tufa-grave. Among the contents of this tomb was an artificial leg, made of bronze, wood, and iron, the skeleton being entire save the bones represented by the artificial limb. This (probably unique) relic is now in the Museum of the Royal College of Surgeons of London, and is thus officially described: "Roman artificial leg. The artificial limb accurately represents the form of the leg. It is made with pieces of thin bronze, fastened by bronze nails to a wooden core. Two iron bars, having holes at their free ends, are attached to the upper extremity of the bronze. A quadrilateral piece of iron, found near the position of the foot, is thought to give strength to it. There was no trace of the foot, and the wooden core had nearly all crumbled away. The skeleton had its waist surrounded by a belt of sheet bronze, edged with small rivets, probably used to fasten a leather lining. Three painted vases (red figures on a black ground) lay at the feet of the skeleton. The vases belonged to a rather advanced period of the decline in art (about 300 B. C.)." Commenting on the above, General H. H. Maxwell says: "It is important to add, from other sources, that the upper third of the leg was hollow, while the lower two-thirds were filled with wood."

The Napoleon (III.) of Medical Editors.

Our valued colleague, Dr. George F. Shrady, of the New York *Medical Record*, has, we are glad to say, greatly relieved us by stating that the clipping we took from the New York *Tribune* (see Med. and Surg. Reporter, January 22, p. 127,) had been to him unknown and unseen. He adds that the operation was performed several years ago, and that the notice must have been of ancient date.

We will give another clipping, this time also from a New York daily paper, and no longer ago than Monday, January 24, 1887. It is from the New York *Mail and Express*, and its editor so bubbles over with admiration for our valued colleague that he leads his editorial column with this article:

Dr. Geo. F. Shrady, the physician who is piloting Father McGlynn through the shoals and quicksands of a dangerous illness, was born in this city some fifty years ago. He and Father McGlynn attended the same school, and the warmest relations have existed between them ever since. When, about a year ago, the priest began to find his physical powers fail him, he went to his old playmate for advice, knowing that he would find not only a physician but a friend. Dr. Shrady looks very much like Napoleon III. He wears the same moustache and imperial goatee, and has the same Roman nose. In stature he is short. His head is broad at the top, and his eyes are deep-set and clear. His manner is always courteous, and his speech nervous and picturesque. Dr. Shrady, it will be remembered, was one of the physicians who attended Gen. Grant throughout his long illness. As a surgeon, he stands very high among his fellows. He is attached as consulting surgeon to many of our hospitals, and his private practice is large and lucrative. Perhaps he knows more of Dr. McGlynn's private affairs than any other man in the community.

"Napoleon" is good, very good! But, alas! Napoleon III.! We propose a nickle subscription to have a wood-cut of our distinguished colleague printed in the *Mail and Express*. We should feel encouraged in our labors by gazing upon his Roman nose and imperial goatee. Shall we have the pleasure of being again the first to bring this tribute of admiration also to the knowledge of our fellow-editor?

How Shall the Death Penalty be Inflicted?

At a meeting of the New York Society of Medical Jurisprudence and State Medicine, held January 13th, the subject of discussion was "How Shall the Death Penalty be Inflicted?" It was opened by Dr. N. E. Brill, who read a letter which he had received from the Committee on Capital Punishment appointed by the State Legislature, asking his views on the subject. In reply he stated that he had expressed the opinion that hanging was barbarous; quoting Dr. Hardy, who had attended numerous executions by this method, to the effect that he never in a single instance saw death occur by a broken neck. Dr. Brill considered the most humane method that of the guillotine, and said that he was opposed to electricity because dynamos were too expensive; to prussic acid because its action was indefinite and often caused violent convulsions; and to the garotte because it frequently failed. Among those who took part in the discussion were Dr. John C. Peters, who favored the garotte; Dr. McLaurie, who advocated carbonic acid gas; Mr. W. H. Russell, who thought the criminal should be delivered over to a commission of selected scientists who should take his life in the interests of science; and Dr. Wood and Mr. D. S. Riddle, who believed that the present method of hanging was not necessarily brutal, and that it had more effect in deterring others from committing murder than would be the case with any of the other proposed plans.

Carlyle on the Medical Profession.

In a letter written to Dr. Hutchinson Stirling in 1842, and but recently published, Carlyle said of the medical calling: "What profession is there equal in true nobleness to medicine? He that can abolish pain, relieve his fellow-mortal from sickness, he is indisputably usefullest of all men. Him savage and civilized will honor. He is in the right, be in the wrong who may. As a lord chancellor, under one's horse-hair wig, there might be misgivings; still more, perhaps, as a lord primate, under one's cauliflower; but if I could heal diseases I should say to all men and angels, without fear, 'En! ecce!'" Carlyle also gives some good advice on the subject of writing *versus* working. He counsels his correspondent, Dr. Stirling, then a young man, to "learn the indispensable significance of hard, stern, long-continued labor," and of silence. "Be in no haste to speak yourself," he says. "Why be *porous*—incontinent? Nothing can foment itself to clearness in a *colander*." Avoid literature, he continues, which, as a trade, is the "frightfullest, fatalest, and too generallydespicablest, of all trades now followed under the sun."

A Dangerous Operation—for the Doctor.

Dr. Souchon (*Texas Medical Journal*) relates a case of abscess of the axilla which was incised while the patient was only partially under the influence of the chloroform. As the knife penentrated the flesh, the patient sprang to his feet, rushed at the case of instruments, which was near by, and had half opened a drawer and was about seizing an instrument, when one of the students bravely caught him. He very soon quieted down. The next day he said that he had just come from a grinding on a sugar plantation where a number of Chinese were employed; that he

was always quarrelling with them, and that as he was going under chloroform, the students around him became gradually transformed, in his mind, into Chinese; and that as the knife penetrated him, though he felt no pain, he was satisfied it was one of the Chinamen who had stabbed him. Hence the rush he made to what he thought was his armory, for a weapon to defend himself.

Small-Pox in New York.

The *Med. Record* tells us that small-pox has appeared very suddenly and developed with much rapidity in that city. Up to January 11, 1887, there had been but one case reported during the winter. In the next week there were twenty-five cases reported, with two deaths. Up to Monday of last week there had been thirty-two cases reported, which is more than have occurred in the city since 1882, as shown by the following table:

Years.	Cases Reported.	Deaths.
1881	1,342	451
1882	708	259
1883	26	12
1884	5	—
1885	105	26
1886	109	31

The source of the present contagion seems to have been mainly in the neighborhood of West Fiftieth street and Seventh avenue. A few cases have been contracted on shipboard and brought through the quarantine before the disease had made itself known. Yet another source seems to have been the mysterious case of the Mauri family, in Brooklyn, to which it is thought a few of the earlier cases may be traced.

The University in the Cabinet.

The class of 1819 of the University of Pennsylvania sent two of its members into the national cabinet. Henry D. Gilpin was Attorney-General under Van Buren (1837–1844), and Robert J. Walker was the noted free-trade Secretary of the Treasury under President Polk. Mr. Walker was the first to suggest the Presidency of General Jackson, and was a sturdy supporter of "Old Hickory." He advocated the acquisition of Texas, and urged the divorce of the government from the banks. His celebrated report in favor of free-trade was reprinted by order of the British House of Commons.

The Pasteur Institute.

At a recent meeting of the General Council of Upper Alsace, M. Boch proposed that a grant should be made in aid of the Pasteur Institute for the Preventive Treatment of Rabies. M. Boch recalled the fact that the first cure effected by M. Pasteur was that of a young Alsatian, John Meister. The Council requested the Government representative to put aside a sum, out of the 12,000 marks accorded to public charities, to be presented to the Pasteur Institute, for the treatment of Alsatian subjects.

British Gynecological Society.

At the annual meeting of this Society on Wednesday, January 12, Dr. Bantock was elected President for the present year. Mr. Lawson Tait gave a farewell address as President for 1886, in which he referred to the work done by the Society, especially in relation to the true significance of menstruation. He also vigorously defended the operation of removal of the uterine appendages, when performed in suitable cases, and expressed regret that some leading authorities offered so much opposition to this operation.

New York County Medical Society.

The annual meeting of the New York County Medical Association was held at the Carnegie Laboratory January 17, when the following officers were elected:

President—Dr. John Shrady.

Vice-President—Dr. J. R. McGregor.

Recording Secretary—Dr. P. Brynberg Porter.

Corresponding and Statistical Secretary—Dr. Glover C. Arnold.

Treasurer—Dr. Charles Ellery Denison.

Member of the Executive Committee—Dr. Edwin Saunders.

A Tramp of Most Heroic Mould.

Woman (to tramp)—"I kin give ye some cold buckwheat cakes an' a piece o' mince pie."

Tramp (frightened)—"Wha-what's that?"

Woman—"Cold buckwheat cakes an' mince pie."

Tramp (heroically)—"Throw in a small bottle of pepsin, madam, and I'll take the chances."

The Cholera's Ravages in South America.

The Secretary of State has received despatches from Buenos Ayres stating that the deaths from Asiatic cholera in that city in November last were ninety-three, and that business is virtually suspended there. The

death-rate in Rosario has sometimes reached fifty per day. The goverment authorities are working energetically to extirpate the plague by modern methods.

When You Have Eaten Rabbit.

"Yes," said a Madison street butcher, "You've seen dead rabbits hanging in front of this market for the past ten years, but they are not the same rabbits. Oh, no. Do we ever sell any? Once in a while. You have eaten rabbits, haven't you? No? Oh, I guess you have. Ever eat canned chicken? I thought so. Then you have eaten rabbit."

War as a Therapeutic Agent.

Montaigne relates that Jason Phereus, being given up by his physicians for an abscess in his chest, and wishing to make an end of his life, threw himself headlong into a battle in the midst of his enemies. He received a wound through the body which emptied his abscess, so that it healed and he recovered.

A Horse in Spectacles.

In a paper on near-sightedness, lately read before the New York County Medical Society, Dr. W. F. Mittendorf told of a fine horse in Berlin that became intractable, and on examlnation proved to be suffering from myopia. The owner had a pair of glasses made for it, and it became as tractable as ever.

Personal.

—Mrs. Clara Doane, of Harwichport, Cape Cod, celebrated her 95th birthday on the 26th of last month. She received her guests with an old tobacco pipe in her mouth, and smoked throughout her reception. She said to one of her horrified lady callers: "I've been a-smokin' now nigh on to eighty years, and if there's anything that's kept me alive all these years it's tobacco."

—Dr. Edward H. Leffingwell, of New Haven, Conn., now over eighty years of age, has a collection of autographs and engraved portraits, for which he has paid not less than $20,000. In early life he was professor of toxicology in a Missouri college. He subsequently visited Peru, where he married a lady of high family.

—Dr. Thompson Westcott, resident physician of the University Hospital, has temporarily resigned on account of ill-health.

—Dr. C. Jones Irvin, late of the Episcopal Hospital, has been elected resident physician at the Orthopædic Hospital and Infirmary for Nervous Diseases, Seventeenth and Summer streets.

—Dr. J. M. Anders, of this city, gave an interesting lecture before the Young Men's Christian Association, of Camden, last Saturday evening, his subject being "Food, Its Use and Abuse."

—Mr. Cleveland has been invited to attend the Mardi Gras festivities at New Orleans. Rex has conferred upon him the title of Duke of Washington, and through Bathurst, his Majesty's Lord High Chamberlain, advised him of the honor and presented him with his insignia of rank. The badge is of exquisite design, and the letter accompanying it is of a witty character.

Items.

—A druggist is not inappropriately termed the pill-ar of society.

—The following terse note was recently left behind an eloping couple in one of the Hampshire hill towns: "We've eloped. Forgive us if you can, and if you can't, what will you do about it?"

—The Madras Government is about to engage in the cultivation of jalap. The demand last year from the Madras Medical Department was for 1300 pounds, and only 400 pounds could be obtained from private growers.

—According to Spanish journals there is at present in Logroño a medical man, Don Rosendo Recondo, still in considerable practice and in the enjoyment of good health, who if he lives till next February will be 100 years of age.

QUERIES AND REPLIES.

REMEDY WANTED FOR SPERMATORRHŒA.

EDS. MED. AND SURG. REPORTER:

I have just received a letter from a patient asking me to send him a prescription for a "certain sure *undiscovered* remedy for spematorrhœa." If any of your readers know of such a "remedy," please have it placed in the query department of the REPORTER. W.

LEAD SOLUTION.

EDS. MED. AND SURG. REPORTER:

If E. I. P. will boil his lead solution in a porcelain dish for fifteen minutes and then add sufficient hot water to make up deficiency for evaporation, it will restore it.

SOLUBLE
PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by
ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1154-1556

Platt's Chlorides
THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant. Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

THE DIFFERENTIAL DIAGNOSIS OF CANCER IN THE MESENTERY.*

BY W. C. VAN BIBBER, M. D.,

Of Baltimore.

It was a surprise to me, whilst making some investigations connected with this paper, to find that the differential diagnosis of cancer in the mesentery may almost be considered as a new subject. To present the matter clearly, there are so many points to be submitted for consideration, and such a necessity that each one should follow the other in a proper sequence, that there is evidently a choice of ways in which the subject may be presented.

Fortunately, the high authority of Lord Verulam is applicable to such an emergency. He advises to commence by what he terms "the opening of the way." By this is meant a statement of the facts connected with the case, and of these facts, I have a record of three cases with which to begin.

Case 1. Miss Mary B., æt. 23, had been healthy as a child, a girl, and a woman, until about the middle of November, 1884. She was at that time engaged in teaching school, and being placed under favorable circumstances, there was no known cause to which her sickness could be attributed. She commenced by complaining of pain in the back. Soon the pain was referred to the left side, and gradually became more diffused and incessant. Yet as to location, it was always referred to the left side; sometimes in the hypochondriac, then in the lumbar, and sometimes again in the iliac region. The pain was always described as a deep-seated, internal, never-ceasing pain. Of its character there was less uniformity; sometimes it was said to be lancinating, making her cry out. Again, it was steady and constant; sometimes shifting from point to point, over a surface embracing the three regions mentioned. She had been attended during the course of her sickness by several physicians, who had tried many means of alleviating this pain, but without success. Finally, whilst Dr. J. Houck was her attending physician, I was called in consultation. I first saw her on the 10th of February, 1886, after she had been sick and under treatment for about a year and four months. I had no difficulty about expressing a diagnosis. A large tumor in the left hypochondriac region, with well marked pointing and fluctuation over the middle of it, accompanied by pain, a weak, thready pulse, and a general cadaverous appearance of the patient, left no doubt in my mind that it was an abscess, and most probably of the spleen.

To my great surprise, however, Dr. Houck's longer study of the case had taught him to think quite otherwise. "There can be no abscess," said Dr. Houck, "because at no time has there been any rigor, and the thermometer has never been above normal, but, on the contrary, most frequently it has been sub-normal."

Notwithstanding this evidence, such was the firmness of my conviction, that, at my earnest solicitation, it was agreed to return the next day and aspirate the supposed abscess.

*Read before the Baltimore Academy of Medicine, January 18, 1887.

In the meantime warm poultices were ordered to be applied to the spot where "pointing" was then so distinct.

When we returned the next day, the appearance of the parts had entirely changed. The size of the tumor had subsided, there was no longer any pointing, or perception of fluctuation. Such a change was scarcely credible; so that the needle was passed deeply in at the point where fluctuation was so distinctly felt the day before. No pus was obtained.

Prof. S. C. Chew saw the patient with Dr. Houck and myself on the next day. He declined making a diagnosis. The patient died on the 20th of February, 1886. On the 21st, when we were assembled for the autopsy, I again committed myself to the diagnosis "of an abscess somewhere, most probably in the peritoneum." Drs. Houck and Chew again declined committing themselves to a diagnosis.

The autopsy was made by Dr. Claude Van Bibber, who has furnished this report. "Body emaciated and pale. Only the abdominal cavity opened. Immediately on dividing the peritoneum a large hard mass presented in the umbilical, the left hypochondriac, and lumbar regions. Examination showed this to consist of the mesentery, which was immensely enlarged, and as hard as cartilage. It was irregular in shape, and involved in the disease was the left kidney, enlarged to the size of a cocoanut, and very hard. On section, its tissue was dense and fibrous, no trace of kidney structure remaining. The right kidney was enlarged, but upon section, the structure was normal. The small and large intestines were completely devoid of fat, had a thin and shrunken appearance. The other organs were normal."

Dr. Chew took the specimen to the Johns Hopkins University to have it examined microscopically. It was the intention to exhibit it to this Academy with this paper, but unfortunately the specimen has been lost.

Case 2. H. Sardine, æt. about 65, whose disease was of more than a year's duration. He was a private waiter, temperate, well and comfortably provided for, and no adequate cause could be assigned for his sickness. His early symptoms are indefinitely described, but consisted for the most part of constant and deep-seated pains in the abdomen with constipation. When the bowels were forced by purgatives the pains increased, and toward the last were principally in the rectum. For these reasons, and also from the character of the moulded fæces, the diagnosis of his physicians was "stricture of the rectum."

Dr. Nathan Gorter, assisted by Dr. Claude Van Bibber, made the post-mortem examination of this case. Their detailed report of the autopsy is long and minute, so that those points only which apply to the subject now under consideration will be given. The report says: "The mesentery was the part most completely involved in the disease. It was harder than cartilage, and equally without vascularity. It was four inches thick, and twelve inches broad. It pushed the other viscera from their situation *in situ*. The meso-colon was largely diseased, as also the meso-rectum, which gave reason for the diagnosis of "stricture of the rectum."

Case 3. Mr. F., which I reported in the *Transactions* of the Medical and Chirurgical Faculty of Maryland, in 1876. The diagnosis before the death was "cancer of the omentum." The autopsy was made by Dr. C. F. Bevan. A synopsis from his report says:

"The omentum was small and atrophied; stomach, liver, spleen, pancreas and kidneys normal; small and large intestines normal except in size and color. They were thin, shrivelled, and wasted, and of a peculiar pink hue. The mesentery alone was diseased; it was three inches thick by fifteen inches broad. Microscopically, in consistence it was harder than the hardest cartilage. No trace of a single vessel in it could be found. Microscopically, it was examined by Professors Bevan and Tiffany. The cells found were of a mixed and undefined character."

I have not been able to find any case like this on record, and more will be said of it hereafter.

There are three cases and three autopsies. The scalpel revealed three cases of cancer of the mesentery.

There were three mistakes in diagnosis. One case was mistaken for abscess of the spleen; another for stricture of the rectum, and the third for cancer of the omentum. The object of this paper is to show, if it is possible, how cancer of the mesentery may be recognized with greater certainty.

So far as my study of the subject has gone, this is a point which needs elucidation and authority.

Without tracing the subject further back than 1855, the date of the issue of "Copeland's Medical Dictionary," which was supposed to be the most comprehensive book of its time, I fail to find in it, or in any of the many excellent systems or compendiums of the practice of medicine which have been published since, or even in any of the spe-

cial works upon diseases of the abdomen, any detailed assistance towards "the differential diagnosis of cancer of the mesentery." It is casually mentioned in some of the authorities, but not especially dwelt upon.

Yet, I cannot assert, that much more than I have been able to find, may not yet be contained in the wealth of the National Library, or referred to in the "Crœsus" pages of the Index Medicus.

He who has more of the excellent and exceeding virtue of the patriarch of old than I have, or whose days go further towards the days of the son of Enoch than any of us can expect to go, must complete the search, and correct me, if I am wrong.

The suggestions which will now be made concerning the differential diagnosis of cancer in the mesentery and the points to which attention will be called, are, the frequency of the disease, some of its anatomical peculiarities, its duration, its symptomatology and pathology.

One point to be taken into consideration in the diagnosis of any disease is its frequency. The importance of any disease in general practice is also measured, in some degree, by its frequency.

In what proportion of the cases of abdominal disease mesenteric cancer occurs is, as yet, not numerically established. The data which I can give, or have been able to collect, on this point, can scarcely as yet be considered as even a basis for conjecture.

The number of autopsies which I have made in my own private practice, together with those at which I have assisted in the private practice of others, amount to 152. Of these, three deaths have occurred from malignant disease of the mesentery. But this will give no real data for the proportional frequency of this disease, because the autopsies made in private practice are only occasional opportunities, and are principally of recondite cases, of which a diagnosis during life was most difficult.

Of the 152 post-mortems, 68 were of abdominal diseases. In 1, the mesentery alone was affected. In 2, the mesentery was so much more affected than any other organ that it was reckoned as the cause of death. In 7 other cases the mesentery was, more or less, involved in the malignant disease. This gives for the 68 cases 14.7 per cent. of mesentery disease. This may be considered too large a proportion for abdominal diseases generally; but it is intended to approximate to the proportional figure for malignant diseases of the mesentery when other abdominal organs are involved.

The next point to which attention will be called is what assistance can be obtained for the diagnosis of mesenteric cancer from a study of the anatomy of the part.

It will be admitted, upon reflection, that the means to be commanded, and the physical explorations which can be used to facilitate the diagnosis of disease of the mesentery are necessarily limited. The exclusion of other diseases holds a more prominent place in this than in the diagnosis of almost any other organ. Otherwise than by exclusion, the diagnosis must be made entirely from symptoms which must be studied.

In order to show this important point more clearly, let me recall to you a few points in the anatomy of the mesentery. M. Sappy, who is high authority upon the anatomy of the viscera, says: "In measurement, the plane of the normal mesentery is not larger than the hand. It is six inches long by four in width. It is a membranous pedicle to which the convolutions of the intestines are attached upon its movable border. This pedicle, of an irregular quadrilateral figure extends from the left side of the second lumbar vertebræ to the posterior border of the cæcum. Its direction is not vertical, but a little oblique from top to bottom, and from right to left. It is highest in the middle part and arches to its extremities. Firmly attached posteriorly, it undulates with a fluted border, and has been compared to a fluted cuff, the outer edge of which bears, like a ruffle, the small intestines from the jejunum with the ilium to the cæcum. The mesentery is formed by a folding of the peritoneum two blades upon each other. Between these blades, from the base of the pedicle, run voluminous arteries, corresponding veins, lymphatic ganglions, and a quantity of cellular tissue. Such are the parts which compose this membrane." The anastomoses of the arteries are free and numerous. They anastomose with the colic, the sigmoid, and the hemorrhoidal arteries.

A knowledge of its anatomical peculiarities, as compared with those of other organs, may assist the study of its diagnosis in disease.

It is important to observe that, as a pedicle, the mesentery is attached behind, to a thick and hard base, and cannot be approached by the sense of touch from any direction. It is not possible to reach it by sight or sound, therefore, the senses are excluded from our means of diagnosis.

In order to show yet more clearly the difficulties to be encountered in the diagnosis of disease in the mesentery, let it be com-

pared, in this respect, with the diseases of the viscera in the other three cavities of the body.

In the encephalon, some of the means now relied upon for a diagnosis are the knowledge possessed of the localized functions of the separate parts of the two brains, together with the tracings of the nerves which go out from these organs. This, in its entire embrace, is one of the most absorbing studies of the day, and is being advanced with industry.

The means for the diagnosis of the diseases of the viscera within the cavity of the thorax are amply facilitated by four of the senses.

The viscera in the cavity of the pelvis by the same, and even more largely assisted by other means, especially by instruments.

But the changes which occur in the mesentery cannot be thus aided by physical exploration. Other means must be relied upon.

What is the function of the mesentery? Although it is necessary to the support of human life, it has no active function. It simply serves as a support, or a table, for the transmission of vessels going to organs which sustain life. When a free flow through these vessels is being gradually obstructed, health must be impaired, and finally, when completely obstructed, life must be extinguished. A knowledge of what changes may occur while this process is going on is worthy of study, and to assist in demonstrating this point, there are three prominent analogues of similar pedicles and pediculated bodies, to be found in the human body. These are the roots of the lungs, the spermatic cord, and the ovaries. It is scarcely within the range of fair anatomical definition to speak of the neck as the pedicle of the head, although in certain diseases of the neck the circulation of the blood, in the head, is impeded.

The lungs have no vascular connection with the body except through their roots. They are otherwise completely isolated. All that enters into the parenchyma or substance of the lungs in health or in disease, or what is removed from them in this latter condition, must pass through the roots of the lungs. Diseases in the roots, as well as in the substance of these organs, may be recognized by various means of diagnosis, and it is known that when the disease involves the root the body of the organs beyond suffers in a peculiar manner. The peripheral circulation, both of ingress and egress, are impeded, and those who treat diseases of the lungs with these facts before them have advantages. In pneumonia, for example, how can the masses of plastic deposits be removed except through the roots of the lungs?

The same may be said for the testes and the spermatic cord. I am now treating a case in which the circulation through the spermatic cord of the right side is nearly obliterated. and the testicle upon that side is correspondingly affected.

The diseases of the uterine ligaments, which transmit vessels in the ovaries, are sometimes difficult to diagnosticate, but these are more easily reached than the mesentery, and the rules which govern the diagnosis in the one case cannot all be applied to the other.

Duration of the disease. There is but little certainty as yet upon this point, because there are not enough cases collected from which to obtain an average. It may be said, as a rule, that cancer is a disease of long duration. In my own cases, all three of them were under treatment more than a year. The nearest approximation to which I can arrive is 40 months for the three cases. This gives an average of 13.3 of a month for each case. The difficulty consists in not being able to determine the initiation of the disease. By what train of symptoms, when grouped together, may the disease be first suspected?

A rule which may be applied to the answer of this question may be expressed somewhat in this way. Granting that an existing disease, in any individual, can be fairly located in the abdomen; then, if it be obstinate, unrelievable, and progressive, malignancy may be suspected or inferred. Again, if in the progress of the disease the symptoms do not show by well known pathognomonic and individual symptoms that other organs are involved, as for example, the stomach, the liver, the pancreas, spleen, or kidneys, then it may be inferred that some rarer form of disease exists. Such a train of reasoning may, by being closely followed, finally lead up to the opinion that there is cancer of the mesentery.

What are, besides these, its own pathognomonic symptoms? The three cases which I have reported had one symptom in common. But the third case given, viz., that of Mr. Fondriat, is remarkable. So far as I can find out, it stands solitary and alone, in the fact that the mesentery was the only organ found involved in the malignant disease. The post-mortem was made most carefully, and in the presence of many experienced physicians, hence the history and prominent symptoms of this patient may be interesting.

He was 68 years of age, and of a strong and

healthy figure. His occupation had been formerly a distiller, and latterly a lace finisher. He had always been temperate. His symptoms from the beginning to the end were those of an aggravated and increasing indigestion, or dyspepsia. He had constant uneasiness in the abdomen, and many acute and prolonged pains. These pains were always referred to the region of the mesentery. The most painful symptom was an obstinate constipation. For the relief of this he used powerful purgatives and enemas. The action of these remedies was invariably attended with intense suffering, and generally with the expulsion of a small amount of fæcal matter. He had disturbed sleep, anorexia and emaciation. He had beside these many other wandering pains, but the great peculiarity of his pain, and also that of the other two cases, was that of being deep-seated, constant, sometimes acute and lancinating in character, at other times dull and wearing. These pains were always referred to the region of the mesentery. Under anodynes the pain would be ameliorated, but only to return as the anodyne effect wore off.

This is what may be said for the symptoms: concerning the pathology of the third case reported, it may be considered a rare opportunity and a treasure. The mesentery was the only organ involved. It is a solitary case, consequently the pathology of the disease, so far as I can give it from my own knowledge, must include only this one case. All the other cases had complications.

It was well put by Professor Bevan. "The small and large intestines," he said, "were normal except in size and color; they were thin and shriveled, and of a peculiar pink hue."

This might have been anticipated from the nature of the disease.

All blood supply and vital activity had been cut off from the intestines.

The same fact and illustration of the same principle may be seen in nature every day. They may teach us.

A full-blown flower, when the circulation of its sap is impeded by a disease or a break in the stalk, shrivels and changes its color as it dies.

There is another law supposed to govern the frequency of cancer in the abdominal organs, which should be mentioned. It is this, that the abdominal organs are attacked, with malignant disease in numerical frequency, according to the supposed activity of their physiological functions. Thus, first the stomach, then the liver, third the intestines, and of these lattter the most frequent points for malignant diseases are the cæcum, the sigmoid flexure, and lastly the rectum.

Judged by this law of function alone, malignant disease of the mesentery might reasonably be expected to be of rare occurrence.

Concerning the diagnosis of cancer of the mesentery, I have shown that in frequency it may be expected in 14.7 per cent. of all malignant abdominal diseases. If it is thought that this is too large a proportion, time and further observation will prove it to be so.

It must be remembered that this is an approximation to the number of cases where the mesentery is involved in the malignant disease together with other organs, not where it is primarily affected and the sole organ diseased.

I have endeavored to show not only how a study of its anatomy as a pedicle, and its use as a support for the circulating vessels of the intestines, may assist in the matter of a diagnosis, but I have tried also to show how its study together with its analogues as a pedicle may illustrate many practical points of interest and usefulness.

Further than this, I have shown what character of pain may be expected to demonstrate the disease, and how the diagnosis may be facilitated by a careful study of the character of the pains.

In the single case which has been brought forward so frequently, it is believed there is not one like it upon record, and it well deserves to serve as a starting point in the study of the differential diagnosis of cancer of the mesentery.

ON THE USE OF WHALEBONE BOUGIES IN THE TREATMENT OF URETHRAL STRICTURES.*

BY J. H. BRINTON, M. D.,

Professor of Surgery, Jefferson Medical College.

I propose, for a few moments, to ask the attention of the Society to some points in the application of filiform bougies to the treatment of urethral stricture, although it is not my purpose to institute any comparison between other modes of treatment and that of which I shall speak. I wish merely to refer to the process of rapid dilatation, effected in the course of a few minutes, by the introduction of stretching instruments, the employment of which is preceded and accompanied by the use of filiform bougies. When these

* Read before the Philadelphia County Medical Society.

latter were first introduced they were warmly welcomed, but I think that of late some disappointment has been felt in regard to their efficiency, a disappointment which, however, I do not share. I believe that in these instruments we have an efficient mode of treating stricture, provided they be properly constructed, and skillfully manipulated.

As I have never been quite satisfied with the whalebone filiforms of the shops, I have for some years been in the habit of making my own, and with these I have experienced comparatively little difficulty in treating stricture, and in relieving obstinate cases of retention. My experience has convinced me that all organic urethral strictures of non-traumatic origin are pervious to the filiform bougie, patiently and systematically essayed, and this is the essential and starting point in the treatment which I prefer.

In making my bougies, I purchase the material from a dealer in New York.* These long, slender, rounded whalebones of various thicknesses are articles of commerce, and are used for many purposes in the arts. They are rounded through a drawplate, and come in lengths of twenty-seven or twenty-eight inches, costing about two dollars a gross. Each piece will make two bougies. In preparing them I first cut off the end transversely, so as to get rid of any tendency to split. I then round the end by rubbing it lightly on a sheet of emery paper gummed upon a board. I then make the extremity bulb-shaped. I am told that the bulb is usually produced by the action of a file. This, I think, is objectionable, as it impairs the fibre of the bone, and renders it liable to break or cut when metallic instruments are slid down over it. I make the bulb extremity by placing the end of the whalebone in a groove on the board, and shave or scrape it from the end with a very sharp knife. I then shave down the shank and neck in like manner in the opposite direction, until I have formed a conical neck from three to four inches long and of almost capillary thickness as it approaches the bulb. The shaping of the bulbar end demands some dexterity in handling the knife, and to insure accuracy I do this under a lens of low power. Having shaped the filiform with the knife, it may, if desired, be yet more smoothed by being rubbed laterally on the emery-board. In case cylindrical whalebone can not be obtained from the manufacturers, the irregular strips may be readily rounded by being passed through a watchmaker's drawplate or wire-gauge. As the filiform whalebone bougie is the guide upon which or over which metallic instruments are to be passed, each one should be carefully fitted. This can be done by frequently passing it upward and downward through the tunneled perforation in the beak or extremity of each and every instrument in conjunction with which it may in future be used. This may seem a small matter, but, in fact, the harmonious action of the guide bougie and its metallic companion has much to do in effecting a ready passage of a strictured point. [The speaker here illustrated the process of constructing the bougie.] After using one of these instruments, should the neck become bent or twisted, I place it for a moment in hot water, and then press it in the leaves of a book.

In endeavoring to pass a stricture I make the first attempt with a whalebone: if it passes, well and good. If it does not go through, I follow it with others, perhaps five or six, until the follicles or folds of the mucous membrane near the stricture are occupied. Then by patiently essaying the inserted filiforms, I almost always succeed in getting beyond the stricture at the first sitting. Sometimes, although very rarely, and in non-urgent cases, if great difficulty be encountered at the first trial, and the patient be frightened and irritable, it may be advisable to desist for the day, and to make a subsequent second attempt. Success at the first trial is, however, the rule, if the instruments be well made and the efforts be gentle. There is, however, a caution to be observed as to the time of making use of filiform instruments. Their application in cases of tight stricture should be primary—I mean that one cannot expect to succeed with them if they have been preceded on the same day by the attempted introduction of round-ended instruments, the tendency of which undoubtedly is to obscure or close in some way the narrow opening of a resisting stricture, and thus to render its detection more than usually difficult. I may add here that I always use the straight filiform.

The whalebone, when once introduced, serves as a guide to the metallic catheter, or stretching instrument. This may be the tunneled catheter, or any of the various forms of dilators or divulsors; preferably, I think, that of Sir Henry Thompson, followed by the powerful and most efficient instrument designed by Prof. S. W. Gross, and which registers from 16 to 40 of the French scale.

In using metallic instruments in conjunction with the filiforms, there is one point to

*Joseph F. Tobin, 82 Duane St., N. Y.

which, I think, attention has not been directed. We are ordinarily told to slide the metallic instrument over the whalebone through the stricture into the bladder; in so doing, the whalebone may be cut at the seat of stricture. I have often heard of this accident, and I have seen it happen. I avoid it in this manner: Having passed the whalebone into the bladder, I carry the metallic instrument—threaded on it, as it were—down until I reach the stricture, the point of resistance. I then cease to push the metallic instrument along the filiform, but slightly withdrawing the latter to gain a little by its conicity, I grasp firmly both instruments between my thumb and finger, and gently carry them on together. In this way I am almost certain to pass the resisting point, and, if the stricture be single, to reach the bladder. I speak on this matter somewhat positively, since I have used these instruments largely, and cannot, for many years, recall a case which I have failed to pass in the manner described.

In employing the stretching instrument, I usually separate the blades as far as No. 30 or No. 35 of the French scale, and on its withdrawal introduce a steel bougie of about the same calibre, to see that all is right and that the urethra is clear. The bougie is then removed, and is not reintroduced until the third or fourth day. The after-treatment consists in the hypodermic use of morphia, etc., full doses of quinine, and in a milk-diet.

In retention dependent upon tight and irritable stricture, not readily overcome by the catheter, I have often succeeded by simply passing a whalebone into the bladder, and leaving it *in situ*. The urine will readily pass along the filiform by capillary action, and the steady dribbling thus established will in a short time empty the bladder. The presence of the whalebone serves also to render the stricture less tight, and so facilitates the after-passage of metallic instruments should their use be considered desirable.

RUPTURE OF THE BLADDER.

BY WALTER H. PARCELS, M. D.,

Of Lewistown, Pa.

A case which has excited half the State of Pennsylvania because of its legal and sensational features may possibly possess some surgical points worthy of record. John A., aged about thirty-five, came to my office in October last complaining of cystic irritation. He said he thought an old stricture was troubling him, which had some years before been discovered and dilated by a reputable physician, who regarded it as the result of gonorrhœa. He objected to my passing the sound, as the symptoms were not urgent, promising to have the matter attended to if the difficulty increased. I gave a prescription for some palliating medicine. I had never seen him before. About two weeks later he called, saying that he was somewhat relieved. I did not see him again until the day after Christmas, when I was hastily summoned to his bedside. I found him suffering intense agony, the pain being located in the lower part of the abdomen, chiefly on the left side. He was in too much misery to give an intelligent account of his ailment. I gave a hypodermic of morphia, and after he was slightly easier, began my interrogatories.

I naturally congratulated myself that I had a previous knowledge of the supposed existence of a stricture of the urethra. He said that during the previous night he had had frequent calls to urinate, passing, probably, a tablespoonful at a time. Had suffered some, though not serious, pain during the night and forenoon, which had become terrible about twelve o'clock, or four hours before I saw him. Had, during the forenoon, made a trip to Lewistown (three miles distant), at which place he attempted to urinate, when the pain became so intense that he could with difficulty get home again.

These were all the facts I could get from him, and the throng of fellow-workmen were either unable or unwilling to volunteer any further information, though they were zealous in their efforts for his relief.

He had slight fever, pulse hard and slightly accelerated. The bladder did not seem to be distended, though he claimed that he had passed no water for about five hours, but persisted in his statement that previously, though the amount at each time was very small, the efforts to urinate were so frequent that the aggregate was about the normal amount. What ailed this man? The intense pain, the abdominal tenderness, and, above all, the anxious facies, indicated peritonitis, and so I diagnosed the case. That it complicated inflammation of the bladder I also thought. I was in considerable doubt about the correctness of my diagnosis. The general aspect of the case, however, called to my mind the language of the Ohio M. D., who, when pressed for the foundation upon which he based an unfavorable prognosis, replied, "I feel it in my *bones* that that man is going to die." I saw my patient about an

hour later. He was much relieved of the pain, but the anxious facial expression was still there. I again carefully examined the abdomen for evidence of a distended bladder. I made a careful effort to pass the catheter, but, meeting an obstruction near the prostate, I concluded to defer the operation until morning, inasmuch as I could not satisfy myself that the bladder was at all distended.

A poultice was applied to lower part of abdomen, and I ordered pareira brava and morphia sufficient to control intense pain. I need not detail the medicinal treatment, but simply say that throughout reliance was placed upon the opiate treatment for peritonitis. The following morning I found no urine had been passed yet, and he said he had no inclination in that direction, though the lower part of the abdomen was greatly distended now. With finger in rectum, I succeeded in introducing the catheter, but, to my surprise, I could only draw off a couple of ounces of urine.

In the afternoon, Dr. Harshberger saw case with me. After many efforts, we failed entirely to re-introduce the catheter. The swollen condition of the abdomen above the pubes, and the intense pain and tenderness, and last but not least the fact that no significant amount of urine had been passed for about thirty hours, argued in favor of puncture of the bladder. With a curved trocar I performed the operation per rectum, but was again surprised at the small amount of urine we got. Further efforts to introduce the catheter were unsuccessful, a few drops of urine coming away, and the instrument was left in place. There was some dribbling through the catheter during the night. The following morning the patient was found to be making rapid strides toward another and we hoped better world. Now, for the first time, we learned from outsiders a story which, for nastiness of details, has scarcely a parallel in a civilized community. Here it is in brief:

Christmas day he came to Lewistown and procured a horse and sleigh, and loaded into it three girls of easy virtue and a twenty-five pound turkey. This crowd, all drunk but the turkey, rode a number of miles through a thickly-settled portion of the country, engaged in obscene performances. It is claimed by some that the girls lifted the man out by the penis and tramped upon his abdomen. The sensational newspapers have eagerly seized upon this matter, and some of the reading public think they are rolling upon their tongues some of the sweetest morsels they have tasted since the Beecher scandal. The story has lost nothing by frequent repetition. Our patient's mind was becoming clouded, so we asked him no questions about his Christmas escapade. The following day he died. The girls had previously been arrested and lodged in jail.

The coroner ordered an autopsy, which was made by Drs. Harshberger, McKim, and myself, in the presence of the coroner's jury. The tissues beneath the skin showed strong evidence of external violence. On opening the peritoneal cavity it was found filled with urine. The bladder was empty, and in its upper portion, on the left side, was a *rent* through which I could readily introduce my finger. There was of course extensive peritonitis, which was the immediate cause of death.

There is abundant evidence that the girls threw him out of the sleigh, and that he attempted to get in again, and hung to the sleigh while they drove on. In this way he was dragged along upon his face (which also showed marks of violence), and his bladder being full was probably ruptured at that time. The grand jury found a true bill against the girls, and they will be tried for "murder" at the April term of court.

Had we known that the bladder was ruptured, could we have done more than we did? I say, yes; we could have performed abdominal section, which I think is the surgeon's duty in such a case after he has made a *positive* diagnosis.

OBSTETRICS IN THE COUNTRY.

BY A. D. BUNDY, M. D.,

Of St. Ansgar, Iowa.

Two very interesting letters in the REPORTER of late date on the above subject, induce me to say a few words on the subject. My experience extends over a period of perhaps twenty years, and includes about five hundred cases at term. Practicing in a community largely of foreign extraction accounts for the rather small number of cases, as the majority of them employed midwives, they only calling a physician when nature failed. In about four per cent. of those cases forceps were used. In two cases only, that I positively know of, was the perineum ruptured to the sphincter ani; nor am I aware of any lacerations of the cervix uteri, though I presume there were; nor am I aware that the mother was injured in any other way. I met shoulder and arm presentations four times; of breech cases there were six; of

placenta prævia five cases. I have only to record the death of one woman—that was an arm presentation, and the patient was moribund when I arrived; the child was delivered dead. In one case of breech presentation, in a contracted pelvis, the femur of the child was broken while bringing down a foot.

I use the forceps only when the os is dilated, and when the head ceases to advance. I always take them with me—*i. e.*, the forceps. My craniotomy instruments I leave at home, never having as yet a case for them. I do not use an anæsthetic of any kind, especially in forceps cases. I want the patient to know what is going on. One case of puerperal eclampsia in the eighth month; two cases after labor, all recovering. I carry a cake of Stifel's ½ per cent. sublimate soap and finger brush, and use them thoroughly on my hands before examinations, using the soap to lubricate the fingers or hand. I aim to be surgically and ethically clean.

I have to record only one severe case of septic peritonitis, and a few mild ones; all recovered. I deliver placenta by Credé's method, sometimes aided by extraction. I do not use a binder, but, as recommended by Lusk, use a small bag of salt to lay on abdomen, while patient is in bed; binder to be adjusted when patient gets up, if she desires it. Ergot I give after secundines have passed. Very rarely do my patients suffer from after pain. The cord is stripped and tied, then wrapped in borated cotton.

Such, in brief, is the way I do it. The results seem to be good, and patrons well satisfied, unless it is when the bill is presented—for I charge full prices.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, January 6, 1887. B. F. Baer, M. D., President, in the chair.

The Secretary read

A Report of 616 Cases of Labor in Private Practice,

by Dr. H. H. Whitcomb, of Norristown.

Up to March 31, 1886, I had attended 616 cases of obstetrics. I have had no death of a mother, and only two still-born children; one of these was destroyed by craniotomy. The forceps have been used in two cases only. I have had no case of twins. I have had one case of elbow presentation, one shoulder, one a hand and face, and three breech presentations; all the others were by the vertex. Placenta prævia was present in two cases at full term and in two miscarriages—one at seven and one at five months. Puerperal convulsions occurred in two patients. A series of thirty-two cases of puerperal fever, but fortunately without a single death, followed me in the winter and spring of 1882. The first case occurred after I was in attendance on a case of scarlet fever, and was followed by three other cases; the next two or three obstetric patients escaped, when I was called to attend a woman who was confined while convalescent from erysipelas. The fever developed in her, and then every case I attended that winter and spring suffered from it. Consultation confirmed the diagnosis in all the cases. One instance was after a miscarriage at seven months following pneumonia. The patient had a tedious convalescence. but has since had a child weighing 13½ pounds. I tried to stop attendance on this class of patients, but could not get rid of them. The epidemic ceased as suddenly as it commenced, and I have not had a case since. The smallest child delivered at full term weighed three pounds and lived only three days. Three deaths of infants have occurred from trismus, and four deaths, in children a few days old, for which I was unable to assign a cause. They simply moaned until they died, while they appeared to be in good condition. I had one case of hour-glass contraction and four of severe post-partum hemorrhage at term. My success I ascribe to patient waiting and conservatism. I do as little meddling as possible, and do not use antiseptic injections. The credit is partly due to my old teacher, Prof. Penrose, who is a safe guide to follow. I owe much to his careful instruction. I see so many doctors, who, in almost every case of obstetrics they get, if they arrive before the child is born, put on the forceps to "hasten delivery and shorten the woman's suffering." I am very positive that this frequent use of the forceps is abuse. I have had a number—possibly twelve—of ruptured perineums; they were immediately stitched, with a perfect result in all cases. I have never had a vesico-vaginal, although one of our teachers would impress his classes with the idea that these cases occur in the hands of the country practitioner. I might say the only cases I have ever seen were those in the care of the city doctors.

Dr. H. A. Kelly remarked that Dr. Whitcomb's report was full of interest, and in criticising the observer must be careful not to impose the rules and statistics of an

average Philadelphia practice upon the Norristown people. While it is true that ailing, delicate women live and require obstetrical services in Norristown as elsewhere, yet it is a fact that in Philadelphia the up-town mill population, from all over the civilized world, and the down-town population of pampered society women and alley off-scourings, present very different problems to the accoucheur.

With notable exceptions, labor in the country is *easier*. Differences of the same kind in greater degree exist between our native and the foreign population. I was much struck with this fact this summer when I went to the Anatomical Institute in Leipsic, to Herr Dornfelder, to buy a normal female pelvis. I was going to Berlin to return in a month, and instructed him to find a pelvis as near a normal specimen in the museum as he could in the large amount of material passing weekly through the institute. On my return he gave me a specimen I now have in my office, which was the nearest to the normal he was able to find; and he assured me that a normal pelvis was rare. This dried pelvis with artificial ligaments measures: Sp. I., 25½ cm.; Cr. I., 29½ cm.; Cr., 9 cm.; Dr., 13 cm. The argument as to different necessities in different localities holds with regard to the use of antiseptics.

Dr. Wm. Goodell read a paper entitled

A Year's Work in Ovariotomy.

In it he stated that he had had during the past year fifty-nine laparotomies, but that lest his paper should be too long, he should limit himself to the consideration of his ovariotomy cases. Of these he had had thirty-nine cases, with three deaths.

Of these deaths, one occurred on the table, from the difficulties of the operation. It was a dreadful case of intra-ligamentous cyst with universal adhesions, from which it was shelled out without a pedicle. The ureter had to be dissected out for twelve inches, and the entire colon, womb, bladder, and small intestines, were attached to the cyst. It was a very forlorn case from the start, and he operated merely from a sense of duty. He stated that in the removal of intra-ligamentous cysts the ureter is in great danger, and he believed that it had been repeatedly torn across without the knowledge of the surgeon. Dr. Goodell stated that before the death of this case he had had in succession twenty-two successful cases, and afterwards a series of eight cases before another death took place, viz., thirty-one cases with one death. The second death was due to obstruction of the bowels in a case of large fibroid of the womb and ovarian cyst weighing sixteen pounds. On account of the fibroid, both ovaries were removed. He had had his share of cases of obstruction, but this was the first fatal one in his recollection. The remedies that he used were calomel and belladonna by the mouth, and turpentine by the rectum. The obstruction is due to the adhesion of a knuckle of the intestine either to the stump of the pedicle or to the abdominal wound or to some denuded surface. As soon as symptoms of obstruction presented themselves, he always aimed at once to open the bowels.

The third death occurred in a case of malignant cystic disease of both ovaries in which the operation was incomplete. Malignancy had been suspected, but the operation was forced on him on account of the excessive pain from which the woman suffered. Yet he argued from his own experience and from that of Schroeder and Martin, that, other things being equal, it was always wise to remove ovarian cysts, even when malignant, for patients' lives would be greatly prolonged by the operation.

The right ovarian cyst had no pedicle, but ended in a brittle cancerous mass as large as his fist. This, with very great difficulty, was ligated *en masse*, and then bleeding vessels were secured separately. The left ovarian cyst was so fastened to the womb, pelvis, and broad ligament by masses of cancerous excrescences, that he did not attempt to remove it. He would have abandoned the case after he had discovered the nature of the complications, but he had gone too far to recede, for his hand had been inside of the right cyst to break up its septa, and blood was flowing profusely from it. The lady died twenty-six hours later from shock and hemorrhage.

He stated that some ovariotomists do not report their incomplete operations or their exploratory incisions, but that he thought it fairer to do so. If his memory served him no trick, this was the only incomplete operation for ovarian cyst that he had ever had. None of his cases had been selected, and he had refused to operate in one case only, and that one on account of epithelial cancer of the cervix; so that he did not have any exploratory incisions to report. He had twenty-one cases with adhesions; a very large proportion, which he attributed to the tendency women in this country have of postponing the day of operation. He also had had twenty cases of double ovariotomy; but

this large number was due to his rule of removing the second ovary in all malignant or suspicious cases, in all cases which have passed the climacteric, in all cases of incipient disease, and always when asked by the patient to do so. He further stated that he still adhered to Listerism, and that he used Keith's dressing of one part carbolic acid to seven of glycerine.

Mr. Parish cited a few instances of evil results following abdominal tapping for purposes of diagnosis, or for relief from distention. In his first ovariotomy case, with the view of clinching the diagnosis, he aspirated and withdrew a few drachms of somewhat cloudy ovarian fluid. The patient presented some symptoms which in a few days became grave; pain in the tumor, rigors, rapid and feeble pulse, and high temperature. He operated during the existence of these symptoms and found suppuration of the interior of the cyst, and extensive anterior adhesions—both conditions doubtless dependent upon the aspiration. The patient recovered.

A few years ago a well known medical gentleman of this city aspirated a tumor supposed to be a multilocular ovarian cyst. Though the fluid was stated to verify the diagnosis, the patient miscarried in one or two days of twins at about the fifth month, and the tumor proved to be simply a uterus enlarged by reason of a multiple pregnancy.

I have recently seen in the Philadelphia Hospital a shocking case of labor, in which active labor pains began one week previous to her admission to the hospital. No urine had been voided for several days. Pregnancy was denied by the patient and her friends, and was not recognized by two physicians. The woman was small and deformed, and in the abdomen were two fluctuating tumors, one due to a distended bladder, the other the uterus. Aspiration was resorted to in both tumors, a procedure that was not only unnecessary for diagnostic purposes in this case, but which would probably have been highly detrimental to the patient, had not the neglected and protracted labor already determined a rapidly fatal result. Though tapping for relief, and especially for diagnosis, is less frequently resorted to than was the case a few years ago, yet even now it is too frequently done.

In reference to the development of cancer or sarcoma after the removal of seemingly benign ovarian tumors, I have seen recently an example in a patient operated on by Dr. Hickman and myself. A large cyst of one ovary and a small one of the other, both free from the appearance of malignancy, were removed, and the patient made a tardy recovery. In about a year sarcomatous growths developed in the neck and axilla, and a large one in the abdominal wall of the left lumbar region. The patient died a few weeks ago, and the autopsy was made by Dr. Morris Longstreth, and though the sarcomas referred to were present, there was not intra-pelvic disease. An interesting feature was the total disappearance of the ligature of iron-dyed silk with which the pedicles and several vessels were secured about eighteen months previously.

Dr. H. A. Kelly stated that while simple tapping often was in no way injurious, it was also often productive of grave injury, and one of his own cases illustrated this point very well. The patient having a cyst weighing 100 pounds was tapped in the left iliac region by a notorious homœopathic surgeon. She had previously suffered from pressure symptoms. From now on she suffered from severe inflammatory pains around the puncture, and at the operation the extensive dense adhesions at this point constituted the chief difficulty. She is now well, more than a year since the operation.

It is a cause for mutual congratulations for American operators that their results are becoming so good. The whole credit of this lies in the thorough use of antiseptic agents and the rendering the field of operation completely *aseptic*.

He believes too that our cases at home are more difficult than those now being operated on abroad. The tumors we operate on are older, and with the increasing age of an ovarian tumor occur many changes detrimental to the patient—depression of vitality from pressure symptoms, diversion of so much albumen from the system at large, surcharge of the emunctories, as well as adhesions and unfavorable changes within the tumor itself.

Keith's dressing of a strong carbolized glycerine has rendered excellent results in my hands in at least twenty cases.

Dr. Goodell, in answer to a question by Dr. Baer, said he operated during menstruation merely from pressure of time on the part of the patient, and little or no effect was produced on the discharge by the operation.

Dr. Joseph Price, in commenting on some points alluded to in Dr. Goodell's paper, fearing the contaminated atmosphere of a general hospital, cited the statistics of two hospitals: Special Department of Birmingham General Hospital and Birmingham

Hospital for Women, covering a period from January, 1878, to September, 1885:

Special Department of General Hospital, ovariotomy 35 cases, 11 deaths—31.4 per cent.

Birmingham Hospital for Women, ovariotomy 268 cases, 19 deaths—7.1 per cent.

During the same period the total number of intra-abdominal operations in the Special Department of General Hospital, 85 cases with 21 deaths; mortality 24.7 per cent.

Birmingham Hospital for Women, 632 cases with 49 deaths; mortality 7.7 per cent.

One point as to the value of the spray, quoted from Keith's report of cases treated in the Royal Infirmary, Edinburgh:

CARBOLIC ACID SPRAY CASES.

Ovariotomy, 21 cases; 18 cured, 3 died.

Hysterectomy for fibroid, 2 cases; 2 cured, 0 died.

Battey's operation, 1 case; 0 cured, 1 died.

Twenty-four cases with four deaths—16.66 per cent.

BORO-GLYCERIDE SPRAY CASES.

Double ovariotomy with hysterectomy, 1 case, died.

Hysterectomy for fibroid, one case recoverd. Result with boro-glyceride spray; two cases with one death.

NO SPRAY.

Ovariotomy,	47 cases,	46 cured,	1 died.
Hysterectomy for fibroid,	7 "	7 "	0 "
Battey for fibroid,	1 "	1 "	0 "
Interstitial pregnancy,	1 "	1 "	0 "

56 cases, with one death.

Mr. Keith says: "No cases of serous cysts of the broad ligament were operated on. These all were treated by tapping, and none of them have returned." One such case that Dr. Price saw, died a few days later. Of Dr. Keith's cases, one-half had no adhesions.

Dr. Montgomery expressed pleasure at hearing Dr. Goodell's details and success, and considered his success gratifying, especially after tapping. A patient came to him one month after tapping. She had a high pulse, septicæmia, large adhesions to viscera, etc., putrid clots in the tumor, and died on the fifth day with a temperature of 105°. He does not approve of tapping broad ligament cysts. One patient with such a tumor was tapped seven times. He afterwards removed the tumor, and did not have a single vessel to tie. In this case the peritoneum had been pushed up by the tumor, and was not opened until late in the operation.

Dr. Goodell made a few remarks on the subject of statistics. Dr. Keith's have improved not because he has given up the spray, but because he has grown to his work. Dr. Goodell will give up the spray, because it is an intolerable nuisance. As to the question of malignancy of ovarian tumors, it has been said that "all ovarian tumors are malignant, and should be so treated." This is too sweeping; but the tumors should in all cases be removed as soon as possible, as soon as it is discovered.

Dr. R. P. Harris desired Dr. Parish to report the present condition of the patient from whom he had removed the ovarian tumor exhibited by him before the Society, at its meeting on March 4, 1886, the day after the operation. Dr. Parish requested Dr. Harris, who had seen her much more recently than he had, to report her condition. Dr. Harris stated that notwithstanding the fact that the tumor was largely solid; that it had grown rapidly; that the solid portion had an appearance of malignancy, and that there was a small morbid growth projecting upward from the fundus uteri, the lady was to all appearance a well woman. He saw her on December 26, when she claimed to have perfectly recovered her health and strength, after a very prolonged convalescence. Her appearance and activity certainly indicated that her statement was correct. The uterine nodule must have been a fibroid, as had it been cancerous, it must have materially developed in nine months. The future of this case will be of much interest.

Dr. Chas. Meigs Wilson reported

Three Successful Tait Operations.

These cases are the first of a series performed without the use of carbolic acid solutions for instruments, and without the spray. Hydrant water boiled for six hours was used for the instruments and sponges in the first and second cases, and a solution of mercuric chloride 1 to 8,000 for like purposes in the third. The wounds in all three were dressed after the manner of Keith. The incisions were less than two inches in length. More than three months have elapsed since the operation in each case before it has been reported. It has seemed best to publish the cases in this manner, because the vast majority of all cases recover without accident from the operation, and hence mere statistics of the healing of the wound amount to little but evidence of individual skill. Statistics of the real relief afforded by the operation is what the profession needs in order to give the operation its just place in modern surgical procedures.

Case 1. Myo-fibroma of the Uterus.

This case first came under observation in

July, 1886. She gave her history as follows: Miss McM., æt. 32, nullipara. For the last sixteen months she had a rapidly growing tumor of the abdomen, menses profuse, catamenial intervals ten to fifteen days; for the past four months has been rarely free from bloody vaginal discharge. She was emaciated and anæmic.

She was very nervous and alarmed about the constant bloody discharge. She had reflex pains, but no ovarian tenderness or pain. She was obstinately constipated, owing to the pressure of the tumor upon the rectum. She was found to have a large fibroid tumor of the fundus and anterior wall of the uterus. The enlarged uterus was incarcerated in the cavity of the pelvis, and was very immobile. The sound entered the uterus 7¼ inches. Abdominal section was performed September 20, 1886, with assistance of Drs. E. Wilson, C. P. Noble, D. Longaker. The tubes were as thick as the finger, they had thin walls, and were distended with blood. The ovaries were over-size, and the right one was cystic. The ligature slipped from the uterine end of the left tube, and before it could be secured there was free hemorrhage. The operation lasted forty minutes. Convalescence was retarded by abscess of one of the suture tracts. The patient made an excellent recovery. Present condition: has lost no blood since the second day after the operation; appetite good, and is able to resume her occupation of seamstress; frequently walks two miles to her work; all pain has disappeared; has gained twenty-two pounds since the operation. December 20, 1886, the sound entered the uterus 3¼ inches; the tumor was greatly reduced in size.

Case 2. Hystero-epilepsy.

Mrs. C., æt. 30, primipara. Had always enjoyed good health until after the birth of her child six years ago. She had been delivered with forceps, and the cervix and perineum had been badly torn. She was in bed nine weeks after the confinement. No clear history of her puerperal trouble could be obtained. She has had profuse catamenial discharges since. About six months after the birth of her child she first commenced to have attacks of loss of consciousness, followed by epileptiform seizures at her menstrual periods. These gradually became so violent as to place her life in seeming jeopardy during their occurrence, and left her utterly prostrated. She had been in bed about twenty days out of every month for four years. Her epileptic seizures occurred only at her monthly periods. Everything that her medical attendant could think of had been done for her, and her family were about to place her in an insane asylum. The ovaries and tubes were removed October 3, 1886. The operation was an easy and simple one. The patient made a speedy recovery without any untoward symptoms. Present condition: She is now able to earn her living as a yarn-picker, working full time; has had no discharge of blood; little or no pain; *and not one seizure since the day of operation.*

Case 3. Tubercular Pyo-salpinx.

Miss E. R., æt. 19, nullipara. This patient was also operated upon on October 3, 1886. Since menstruation began, at fifteen years of age, she has had constant dull, aching pain, deep-seated in the pelvis. At her menstrual epochs "her agony has been unbearable." Menses have always been slight in quantity and regular as to time. She presented a badly-nourished appearance. Physical examination showed marked evidence of general tuberculosis. In spite of this fact, and in view of her intense menstrual pain, oöphorectomy was deemed justifiable, and was accordingly done. Both tubes were as large as large bologna sausages, and both ovaries were cystic. Tubes and ovaries were matted in a mass of adhesions which rendered the operation very tedious, it lasting one hour and ten minutes. Microscopic examination of sections of the tubes showed colonies of the bacillus tuberculosis. Both tubes were filled with a greenish pus, which was very offensive. The recovery was complicated by an arthritis, the symptoms of which were so obscure as to render it difficult to say whether it was septic, rheumatoid, or hysterical. She eventually made a good recovery. Present condition: Her physician, Dr. Walter E. Bibby, of Kensington, Philadelphia, reports: "She is entirely free from pain, able to walk about, and to attend to light household duties. Under the use of cod-liver oil and malt and alcohol, her tubercular trouble seems to be making little or no progress." As her peritoneum showed evidence of tuberculosis, as an experiment, bichloride solution (1 to 8,000) was used to wash out the abdominal cavity. Cases 2 and 3 were operated upon before Drs. A. W. Biddle, W. E. Bibby, W. C. Goodell, E. Wilson, Longaker, and C. P. Noble. All were done at the Philadelphia Lying-in Hospital. In each case the abdominal cavity was thoroughly flooded with boiled water before it was closed. The drain-

age-tube was not used. Uncarbolized Chinese silk ligatures and silkworm-gut sutures were used. No anodyne was given after the operation, and no food was given for thirty-six hours after operation.

Dr. H. A. Kelly was particularly interested in the tuberculous tubes, and regretted that an examination of the uterine discharges had not been made, as it would almost certainly have established the diagnosis. As to the right to operate upon a patient having a cavity in the lung, no general rule can be laid down; every such case stands by itself, and much must be left to the judgment of the operator.

Dr. Baer would hesitate for some time before operating in a case of general tuberculosis with a pulmonary cavity. He did not think tuberculosis could cause pyo-salpingitis.

Dr. Kelly remarked that at least two cases have been observed here, and many more abroad, and it has been recently formulated by Prof. Hegar among the tubal diseases which may require operation.

Dr. Parish thinks the general condition of the patient, outside of the pulmonary disease, would decide the question. Severe pain should be relieved, unless the patient had a very short time to live.

Hydrosalpinx.

Dr. H. A. Kelly exhibited the tubes of a patient who had suffered from metrorrhagia over thirteen years. She had been in five large hospitals in Philadelphia, without relief, and had faithfully tried every plan of treatment, systemic and per regimen. The diagnosis of enlarged tubes was made before operation, and on removal, with their respective ovaries, the tubes were found, one as large as a bologna sausage, and the other a small sausage, with a limpid fluid. She has lost no blood since the metrostaxis following the operation about six weeks ago.

Dr. Kelley also exhibited fresh large cystic ovaries and tubes of a large fibro-cystic tumor, upon which he had operated in the morning. The ovaries were sessile, surrounded by congeries of great dilated vessels. The operation was one of extreme difficulty. (*Note five days after operation:* "The patient's condition is perfect.")

The patient whose history was read at the preceding meeting, who had ovaries and tubes removed for chronic subinvolution and endometritis, was presented to the meeting. She has lost all pain, and feels perfectly well for the first time in years. The uterus is normal.

Dr. Parish reported a Porro-Müller operation.

W. H. H. Githens, Secretary.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated meeting, January 12, 1887.

The President, J. Solis-Cohen, M. D., in the chair.

Discussion on Urethral Strictures. (*See page* 197.)

Dr. S. W. Gross said: "I take it that Dr. Brinton has confined his remarks to the treatment of very tight strictures, I think that the younger members of the profession, who are not much accustomed to the use of filiform bougies, ought to be told not to put too much confidence in them. The filiform bougie does not pass with a great degree of readiness through a small stricture, or even through a large one in all cases. I differ from the speaker in regard to the usefulness of the twisted bougies. In the great majority of strictures the orifice is eccentric. A twisted bougie will often pass after we have failed to pass a straight bougie, although the urethra has been packed with them.

"We know that in cases of stricture not the result of traumatism, the obstruction does not arise from the organic stricture itself. A man may have been suffering with stricture for some time, and the calibre of the urethra have been gradually narrowing until the stream of urine becomes very small. In this condition he exposes himself to cold and wet, and in the course of a few hours is unable to pass urine. In such a case the obstruction is not due directly to the organic stricture, but there is superadded spasm of the muscles of the urethra, and it is spasm which we have to overcome rather than the coarctation itself. In such a case, the patient being under the influence of an anæsthetic, I carry a medium-sized instrument, say one whose shaft measures No. 16 and whose point is No. 13 of the French scale, down to the stricture, supporting, if necessary, the curve of the instrument with the finger on the perineum or in the rectum. In the majority of cases gentle pressure for a few minutes will enable the instrument to pass into the bladder. I have succeeded in this way in cases where I have failed to introduce a filiform bougie. A convenient way of passing the filiform bougies is first to pass into the urethra to the seat of stricture a short metallic tube, and then carry the whalebone bougies through this tube.

"I have met with the difficulties referred to in the manufacture of the whalebone bougie. The cutting of the bougie is often

due to the instrument which passes over it. The eye is at times so sharp that it strips up the whalebone. Care should be taken to see that the opening is well rounded.

"In the operation described by Dr. Brinton, which is the one to be used if it is so desired in these cases, it is always well after passing the coarctation and relieving the retention, to bring the urethra up to a certain calibre, and that is another point in the treatment of stricture. How shall we know to what extent we shall divulse or incise a stricture? The operation described to-night is really that of divulsion. I had to-day at my clinic a case in point. It was that of a young man from a distance. He was etherized, and in order to determine to what extent the stricture should be cut or dilated, I introduced into the urethra the urethrometer, with which we can measure the capacity of the urethra. In this case there were two strictures. Immediately in front of the first, which was six and one-fourth inches from the meatus, the urethra had a capacity of No. 31. In such a case, as the stricture always shows a tendency to contract, it is well to cut or rupture it to No. 34 or 35, to allow for the subsequent contraction.

"The instrument to which Dr. Brinton has referred, I had made particularly for the purpose for which he has used it. At the time that I invented this instrument, I was a rather firm believer in the treatment of stricture by divulsion. I do not employ this method now, although I would use it in a case of retention of urine. It is no more dangerous than cutting, and cutting is no more dangerous than divulsion. The cutting can be more accurately limited than the divulsion. With the latter method we tear not only the stricture but also the mucous membrane at some distance in front of and behind the stricture. In a specimen in my possession where divulsion was employed, there were no less than nine rents in the mucous membrane; and the rent in the stricture was oblique and had not gone completely through the stricture. This method will do in superficial strictures, but in hard fibrous strictures we have to supplement this operation for urethrotomy. It is for this reason that I have given up divulsion for internal urethrotomy, and I do not resort to this latter operation so frequently as I formerly did. When the patient is within convenient distance, I much prefer in ordinary cases of inflammatory stricture, and in recent cases more particularly, to resort to gradual dilatation. I have reached the firm conviction that the cases in which radical cure is produced by divulsion, internal incision or external incision, are so rare that it is rarely worth while to resort to these operations."

Dr. Charles B. Nancrede said: "While agreeing with most of what has been advanced by Dr. Brinton, I am rather more in accord with the last speaker. When I intend to do any radical operation I prefer incision, for then I know exactly what I am doing. My experience teaches me that filiform bougies are not always easily passed through a stricture, even when it is of comparatively large size. Where I have failed to pass the filiform bougie, I have frequently succeeded with a metallic instrument of fair size. I have never had to tap a bladder for retention, but have always succeeded, sooner or later, in getting into the bladder with a filiform bougie.

"Although well aware of the eccentric position of the orifice of most strictures, I was particularly struck with the usefulness of recognizing this fact some years ago, in a case of organic stricture in which the urethra had ruptured. Dr. Packard had made several incisions to relieve the infiltration of urine, and when the patient was turned over to me as a hospital case, the larger part of the urine was passed through an opening at one side of the root of the penis. I tried, on a number of occasions, to pass filiform and other bougies, but always failed. I then called a consultation, intending to perform external urethrotomy. Under ether, I again failed to pass my instrument. I asked Dr. Packard to try. Passing the bougie down to the stricture, he carried it transversely to the left, at a right angle to the course of the urethra, passed it in this direction for about half an inch, and then again by a right-angled turn passed the instrument on in the normal direction of the urethra through the stricture, which was not tight. The instrument was tied in, and the patient eventually recovered. In like manner, a twisted filiform bougie may do good service in a tight stricture. I do not think that the filiform instrument is entirely free from danger in the hands of a tyro. There are cases in which the extremity has been caught in a crypt behind the stricture, a false passage made, and this erroneous route has been followed up with other instruments. Whalebone filiform bougies are, however, of the utmost value when skilfully used, and I should feel completely lost without them to fall back upon in a difficult case. Like Dr. Brinton, I have found it necessary to make them myself. I heartily endorse his method

of procedure after the tunnelled catheter or sound has entered the stricture, and have for years resorted to it myself, with invariable success."

Dr. Brinton said: "The remarks which have been made only show that every surgeon operates according to the habit of his own mind and hand. While I do not claim that the method which I have described is better than that of others, I can only say that it is one which I have followed for many years, which has yielded me great success in the past, and to which I look forward with confidence in the future. I believe, too, that uniform success in this procedure can only be secured by the use of properly constructed filiforms, and by the observance of the cautions to which I have referred."

Surgical Mishaps.

Dr. T. Pridgin Teale thus writes in the *Lancet:*

Surgical mishaps are happily not always identical with surgical calamities, as the following three cases, slightly sketched without much detail, will show. The narration may be useful, and may bring comfort to others who meet with similar occurrences.

Case 1. *Disappearance of Tumor after Ineffectual Attempts at Removal.*—I cannot do better than describe this case in the words of a letter which I wrote to Sir James Paget on January 11, 1878: "Mr. H., of H——, consulted me three weeks ago about a tumor behind the angle of the left lower jaw. After existing for several years as a small movable lump, the tumor had within a few weeks begun to grow with an increasing rapidity. It was fairly movable in all directions, and I advised its removal. A fortnight later I went over to H—— to remove it, and then found that the tumor had become at least double in size, was very elastic, and more fixed. I cut down upon the tumor, and found that it involved, and seemed to be growing in, the anterior portion of the sterno-mastoid, and that it had no limiting capsule, as I hoped. Having stripped the outer side of the tumor with the finger, separating it from contiguous fibres of the muscle, I followed it deeply until I could almost touch the transverse processes, where it was firmly attached to deep structures in the neighborhood of the large vessels. I therefore thought it more prudent to abandon any further attempts at removal. Having inserted a drainage-tube, I closed the wound, and all healed satisfactorily. Curiously, the rapid growth seems to have been checked, and this makes me regret that I did not strip the opposite side also, with a view to cutting off supplies." Sir James Paget and Mr. John Wood, who saw the patient, after hearing my description of the operation, agreed that no further surgical interference was advisable, and the former suggested a course of small doses of iodide of potassium, with large doses of liq. potassæ. On April 24, Mr. H. wrote that, apparently under the influence of the medicine, the tumor had decreased so rapidly that ten days previously he had omitted the medicine, and that "it is now scarcely feelable and not perceptible." In December, 1878, he again wrote: "The tumor, or whatever it was, has departed in peace, seemingly never to return." I have heard of him from time to time, but never of any relapse.

December 25, 1886, Mr. H. writes: "The tumor had existed two years before the operation. There is not a trace at present. I took about six bottles of the medicine, and the tumor disappeared in six months."

Case 2. *Chronic Inversion of the Uterus; Attempted Reduction by Taxis; Laceration of Vagina into Douglas's Pouch; Recovery.*—Mrs. J., aged twenty, was sent to me in November, 1884, by Dr. Blair, of Goole, suffering from inversion of the uterus resulting from her second confinement four months before. The labor was prolonged and difficult. She remained in bed for a week after delivery, and on getting up for the first time the womb came down and protruded nearly two inches. The womb was returned, and never prolapsed again, but it was afterwards discovered that she was suffering from inversion of the uterus. The patient was anæmic and frail-looking. In consultation with my colleagues, it was considered that the os and cervix were so much relaxed that I might attempt to reduce the inversion by taxis whilst the patient was under ether. I therefore at once made the attempt, using, as I believed, no immoderate force, and fully realizing the need of caution so as to avoid

the danger of laceration. After careful pressure with the fingers upon the fundus, which in about a quarter of an hour had been reduced to within the level of the os, and just as it seemed that complete reduction was being effected, the whole receded within the peritoneal cavity through a rent in the roof of the vagina posterior to the cervix. I was then face to face with a most difficult problem, and called to my aid Mr. Robson, who was in the Infirmary at the time. After some deliberation, we came to the conclusion that the safest course would be to transfix, tie, and cut off the inverted womb. This having been done, one stitch was inserted into the rent in the vaginal wall as a safeguard against prolapse of the bowels, and a large drainage-tube was inserted within the lips of the wound so as to project for about an inch into the peritoneal cavity, and was fixed by catgut sutures to each side of the ostium vaginæ. The vagina was carefully syringed with weak carbolic acid lotion, and well charged with iodoform. Her further progress was satisfactory. There were never any symptoms of peritonitis. In a few days her temperature rose to about 103°, and then slowly fell, and she returned home within three weeks of the operation. I have since heard that she is in good health, and menstruates regularly.

December 25, 1886, Dr. Blair writes me: "Mrs. G. is quite well, menstruates regularly, and suffers neither pain nor inconvenience."

Case 3. *Wound of Popliteal Artery and Vein during an Operation for Necrosis of the Femur; Recovery without Gangrene.* — A young man, aged about twenty-one, came under my care at the Leeds Infirmary about six years ago, on account of necrosis of the femur. The sinuses led to the back part of the femur, about the bifurcation of the linea aspera. Having enlarged the sinuses, I had considerable difficulty in reaching the denuded bone. In trying to release what seemed to be an indurated edge of the fascia or a ridge of new bone, I passed the knife along this edge, loosening it, as I thought, from its apparent attachment to the bone, when a gush of hemorrhage startled me. To my dismay, the cord proved to be the popliteal vessels coated with a tough, hard case of cicatricial lymph, and both artery and vein were wounded. Having commanded the breach in the vessels by the finger, I sent for my colleague, Dr. Wheelhouse, who fortunately was paying his visit to the wards, and most kindly came to my assistance and gave me timely aid and counsel. Finding it impossible to deal effectively with the wounded vessels through the lateral wounds, I made a vertical incision about four inches long in the middle of the popliteal space, and so exposed the wounded vessels. Having severed the vessels at the seat of injury, I tied both ends of the artery and vein. The whole proceeding was both difficult and tedious. For some days I watched the case with grave anxiety, fearing gangrene and the need of amputation. Fortunately, my fears were disappointed. The foot soon became warm, was never blue, and gave me no cause for anxiety. The wound healed favorably, and the patient recovered the use of the limb. Knowing the frequency with which gangrene results from arrest of circulation through both the main artery and vein of a limb, the impunity which resulted in this case was unexpected, and gave great relief to my mind.

The Physiology of the Harem.

The *Boston Medical and Surgical Journal* says:

Oriental woman has for many generations occupied a position in which the one element of sexuality has absorbed into itself all other qualities and functions of her existence. Sex *et præterea nihil* has represented her value and significance in the national economy, and that not for the primary end of reproduction, but of sensuous gratification. The effects of this condition upon her physical and moral nature have been sufficiently illustrated to the western reader by the concurrent testimony of travellers, and by the coloring imparted to the poems of Moore and Byron. The physiological results of this mode of life have not, however, beyond the general and obvious statement that the women matured very young, been given us in satisfactory detail.

Much has been said of late of the prejudicial effect upon the maternal function produced by extraordinary intellectual activity in women, and it has seemed that the higher education, with late marriages and much study, was not a favorable preparation for fruitful motherhood. But it is not without interest to know that the women of Turkey, educated almost from birth with a sole view to the stimulation of the generative functions, are quite as infertile as the blue-stockings of New England. Dr. Zambaco, of Constantinople, presented a communication to the Gynæcological Section of the last International Medical Congress at Copenhagen, on the general subject of the physiology of

oriental women, which has appeared in the report of the Congress and will well repay perusal, not only from its intrinsic interest, but because of the light which it throws on the effects liable to follow sexual precocity in any country.

Circumcision is practiced, according to Dr. Zambaco, almost universally upon Mussulman girls in all classes of society in Egypt and Arabia. In Egypt, the operation is performed at about the age of seven, as with boys. Great ceremonies attend the event. The girls walk in files or ride in carriages to the scene of the operation, decked in all the finery their parents can give or borrow. The operation is performed by a woman, who makes it her trade. It consists in cutting off the clitoris with scissors, and dressing the wound with hæmostatic powders. The children are taught to look forward to the operation with anticipation, and with their precocious little minds clamor for it as the necessary condition antecedent to their marriage. It is, in fact, indispensable for marriages in these countries, as no man of the lower classes will consent to marry a girl who has not been circumcised. In Constantinople, under the influence of European ideas, it has been largely done away with, at least as a preliminary to marriage, in the families of the government officials and others, though it is said to be common for the husband to instruct the midwife to perform the operation immediately after the birth of the first child.

The Ottoman Empire includes a wide range of nationalities with different habits and religions and climates, the temperature varying from 46° C. to — 30°. Yet the differences in the physiological condition of the women seem not to be racial, or even climatic, so much as the product of social habits affecting the precocity of sexual development. Among the Mussulmans these influences are at a maximum. From earliest childhood the conversation to which girls listen, the whole atmosphere in which they live, is permeated with the one thought of sexuality. Hence menstruation begins at nine or ten years in Egypt, Bagdad, and Arabia. In the Soudan it is even earlier. In Constantinople and its environs, the function is established among the Turkish girls at from ten and a half to twelve years, while in villages a little more remote, where the customs are more rigid, and also among Christians, Armenians, and Greeks, the average date is two or three years later. Circassian slaves who remain in their native land till they are grown up, menstruate at fifteen to seventeen, while if brought when young to Constantinople and exposed to the life of the harem, they menstruate at twelve or thirteen.

In Albania, a mountainous country, where female virtue is well preserved, maturity comes late, at seventeen years. This is the case both with Christians and Mussulmans. The latter are not veiled or sequestered like other Mahometans, and their intercourse with men is on much the same terms as in our own country. The menopause comes late, and they often bear children at forty-eight or forty-nine years of age.

Of course it may be true that the climatic conditions are the primary cause of the tardiness of the menstrual function, but, if so, they act through the medium of quiescent sexual emotions, and the inference from Dr. Zambaco's paper is that such a mental state is not merely the product of a low temperature, but may also result from an unstimulating character of the social atmosphere.

Mussulman women have such a horror of pregnancy as being likely to destroy their shape and beauty, as well as to cause alienation of their husbands in favor of a non-pregnant rival, that abortions are universal. They are spoken of freely in the social and domestic circle, and performed openly and as a matter of course. For these reasons, as well as on account of the incapacity for conception of these overstimulated sexual organs, despite the opportunities afforded by polygamy, the population fails to increase to any extent. It is true that one pasha had eighty-five children by forty-four women, but with increasing poverty of the people, fewer men can afford multiple marriages, and so the births among the Mussulmans are, on the whole, diminishing. Armenians and Greeks, on the other hand, rarely perform abortions, and Jews never.

Marriage among the Mussulman girls takes place usually before menstruation is established, namely, at nine to ten years, and sexual relations are at once established. The result is various local derangements, and *very small fecundity.* One, or at most, two children represents the average productiveness of Mussulman women. The effect of this overstimulation of the generative function is further seen in a premature menopause and early fading. The few women who marry late are also likely to complete their sexual existence early. In the one class of cases the sexual career is shortened through exhaustion; in the other, through lack of function.

The atrophy of the sexual sense is rare

enough in Turkey; we occasionally see it in one of the extremes of our own civilization, where muliebrity has perished from inanition. The Harem and the "Higher Education" may lead, by widely divergent paths, to a common goal, sterility.

Stricture of the Œsophagus.

Dr. Walker Schell thus writes in the *Indiana Medical Journal:*

On the 28th day of September, 1886, I was called to see A, aged two years. The child was very small and badly nourished. She was in great distress, calling for water and milk almost constantly. Whatever was given her was promptly ejected. She was utterly unable to swallow a drop of fluid or food of any kind, and such had been her condition for four days, as I learned from the parents and the physician in attendance. Unless relieved, she would soon perish of hunger and thirst.

The history of the case was such as to make the diagnosis easy. Some months before, the child had accidentally swallowed some concentrated lye. We then had to do with an organic stricture of the œsophagus, the result of a cicatrix. The cicatrix had gradually narrowed the calibre of the œsophagus till, in consequence of some source of irritation of the stricture, deglutition became impossible.

By gradual dilatation I succeeded in passing a catheter equal in size to a number 4on the English scale. She was then fed an abundant quantity of milk. In five sittings I succeeded in dilating the stricture, which was some three inches in extent, commencing at the junction of the pharynx and œsophagus and extending downward, till I could pass a number 14 olive bougie of the English scale.

English bougies with the olive point, such as are commonly used in stricture of the urethra, are in my opinion the best instruments to use for a similar purpose for stricture of the œsophagus, especially in children. They are more easily handled than the œsophageal bougie, and are cheaper. They are sufficiently long for every use which we may have for them in children, and can easily be introduced into the stomach. It is important to feed these cases immediately at the close of our sittings, and for that purpose an English œsophageal tube must be passed into the stomach. Milk and soups are the only food suited to these cases.

The little child whose case I have reported, gained rapidly in flesh, under treatment.

Since the finger must be introduced far into the mouth, it must be well wrapped, otherwise the child will constitute itself into an instrument of torture. This advice is also good in the introduction of the stomach tube in morphia-poisoning, as I have recently had occasion to learn, even where a good mouth speculum was used. The result in these cases is usually in the end unfortunate; still, with proper treatment, life can usually be prolonged, often many years. In most cases, with whose history I am familiar, the parents were negligent, and the child would only be brought for treatment while the symptoms were urgent. The death then usually resulted from some disorder of nutrition.

In cases of malignant disease of the œsophagus, I think, as a rule, gastrotomy ought to be performed, unless the diagnosis is made very late. Of course, the end is the same, but I think life would be prolonged, and many of the most distressing symptoms would be avoided. This I say with the vivid memory of the suffering of one of my first cases in practice before me. It ought not, I think, to be done for organic stricture; at least, not when any instrument can be passed.

Morphia in Diabetes.

Dr. J. M. Bruce thus concludes the report of a case in the *Practitioner:*

When I come to the *conclusions* which may be drawn from these observations, it will be well to arrange them under two heads:

I. *Therapeutical.*—There can be no question that in this case morphine was of value in the treatment of diabetes. Not only did the sugar disappear entirely under the use of the drug, but the patient's weight increased four and a half pounds during the first course of morphine by the mouth, and his personal condition, subjectively and objectively, was greatly improved. It is true, the improvement was but temporary; but it would be equally correct to say that the benefit continued as long as the treatment was maintained. Upon the general subject of the treatment of diabetes by morphine I do not intend to enter. I only wish to recall the attention of the profession to the value in diabetes of a drug which appears lately to have suffered somewhat unfairly in reputation by comparison with codeine.

II. *Physiological and Pathological.*—1. In the case before us *the glycosuria was proved to be due to an increased income of sugar into the blood; not to diminished destruction of sugar in the system.* This conclusion was

established by the fact that whilst the glycosuria was controlled by morphine, the drug had very much less influence on the disorder when it was thrown into the general circulation (where destruction of sugar is accomplished) than when it was introduced into the *portal* circulation.

2. In the present case *the increased income of sugar was proved not to originate in simple transportation of sugar from the intestine or portal vein to the general circulation.* When all saccharine and amylaceous materials had been removed from the diet, the patient continued to excrete as much as 1,360 (later on, even 4,000) grains of sugar per diem. It was clear, therefore, that glycogenesis was still active, and that the sugar was derived from the nitrogenous constituents of the food by some organ—whether the liver, situated on the portal circulation, or the muscles and other viscera, situated on the general circulation.

3. *The excessive glycogenesis that was going on in this case was proved to be effected mainly or entirely in the liver, not in the muscles or any of the other viscera.* This conclusion followed from two facts: (i) That when the morphine was introduced into the liver by the portal vein, it reduced the sugar to *nil*, whilst it did not materially affect the other viscera, such as the central nervous system; and (ii) that when it was introduced into the general circulation it diminished the amount of sugar excreted only to the degree that might have been anticipated from the portion that would reach the liver through the hepatic artery, whilst it markedly affected the other viscera, such as the central nervous system.

4th and lastly, these results appear to prove that in this instance, if the diabetes was of nervous origin (as it is believed to be in some cases), the seat of the disordered process—I do not say the seat of the nervous derangement originating it—was in the liver, not in the central nervous system or nerve-trunks. This conclusion again follows from the effect of morphine by the mouth as compared with its effect *sub cute;* for the subcutaneous method distinctly proved that whilst the central nervous system was profoundly depressed by morphine, there was but little effect on the glycosuria—through this channel, probably *none.*

A Case of Femoral Aneurism Cured after Eleven Hours Intermittent Digital and Instrumental Compression.

Dr. Justin F. Donovan thus writes in the *Lancet*, October 23:

Lorenzo B., a Maltese, aged thirty-eight, a stoker, a well-nourished though anæmic man of abstemious habits, was the subject of syphilis (chancre and non-suppurating bubo) before marriage; secondary eruption was not noticed. On the 10th of June, 1886, whilst coaling ship at Suakim, he experienced a sharp pain in the left groin; this was followed by a swelling, and on presenting himself to the medical officer of his ship, "a pulsating tumor in the left groin was detected, with a distinct bruit." On admission to the Naval Hospital at Malta on the 19th of July, a pulsating tumor, about the size of a small lemon, was seen immediately below Poupart's ligament, and extending half an inch below it (proximal side); no bruit could be detected. The pulsation, which was very strong, could, however, be checked on making forcible compression on the external iliac artery. The patient complained of only slight pain at the seat of the tumor. He was put on low diet, confined to bed, and ordered to take an ounce of iodide of potassium mixture (ten grains to the ounce) three times a day. Pulse 72, temperature 98°; urine free from albumen. On the 26th the diet was reduced to one pint of chicken broth, one pint of milk, four ounces of bread, and ice to suck when thirsty. Iodide of potassium (fifteen grains to the ounce) to be taken as before. Digital pressure on the external iliac artery for an hour and a half was carried out and was borne very well, the part compressed having been previously shaven and dusted over with oxide of zinc powder. On the 27th there appeared to be a slight diminution of the impulse. Pressure (digital, and a pad with a seven-pound conical-shaped weight suspended from a cross-bar and resting on the pad) was kept up for two hours and a quarter, at the end of which time the patient became restless, and appeared to suffer a little from the pressure. Pulse 80; temperature normal. Iodide of potassium (one scruple to the ounce) to be continued. On the 28th, the pulsation in the tumor was markedly diminished. Temperature normal; pulse 84. A hypodermic injection of one-third of a grain of morphia having been administered, digital pressure (assisted by the weight) was applied for seven hours and a quarter unremittingly, and at the expiration of that time no pulsation could be detected in the tumor. In the evening the patient felt very weak; pulse 90, feeble; the extremities were decidedly cold, especially the left foot and leg, although they were enveloped in cotton-wool and a flannel roller; no

numbness or discomfort of any kind was complained of, though there was lividity of the toe-nails and diminution of the temperature of the limb for a few days. Pulsation in the left posterior tibial artery was not detected until August 4 (seven days after the consolidation of the aneurism). Up to the present (twenty-three days after consolidation of the sac) there has been no return of pulsation in the tumor, and the patient is now walking about, and complains only of very slight comparative weakness in the affected limb.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The late Dr. Albert H. Smith occupied a position of deserved distinction among the physicians of Philadelphia. A discriminating and sympathetic description of his life and labors is given by Dr. Harrison Allen, reprinted from the proceedings of the American Philosophical Society.

——"Pneumato-Therapy" is the word applied to the treatment of diseases by the use of compressed and rarefied air. A brief and well-prepared review of its methods and their value is given in a reprint before us, by Dr. Solomon Solis-Cohen, of Philadelphia.

——The therapeutic uses of the new salts obtained from the Karlsbad waters is explained in a large pamphlet lately sent us from Vienna. It is an interesting addition to the balneological literature of the season.

——In a reprint by Dr. H. Hathaway, of Toledo, on the Temperature of the Body in Health and Disease, the author illustrates the thesis that heat is dispersed in tissue-building.

BOOK NOTICES.

The Principles and Practice of Operative Surgery. By Stephen Smith, A. M., M. D., etc. New and revised edition, with 1,005 illustrations. Pp. 877. Lea Brothers & Co., Philadelphia, 1887.

In his preface to this edition the author justly observes that the science of surgery has undergone such extensive changes, even within the few years since 1879, that its aspects are altogether different from what it then was. Operations which at that time were usually fatal, can now be carried out with every prospect of success.

This is chiefly owing to improved methods of antisepsis and to certain advances in strictly operative procedures. Of these improvements, the present edition gives a full account, the author having added largely, to and in fact practically rewritten his original treatise. As it is now presented, it may fairly be said to be as complete an exposition of the science of surgery as is to be found in the limits assigned by it.

The earlier chapters, which are devoted to surgical treatment, especially to anæsthetics and the antiseptic measures now most approved, are especially interesting. The pages throughout are abundantly illustrated, and the extensive reading and clinical experience of the author are evident in every chapter.

Clinical Manual for the Study of Medical Cases. Edited by James Finlayson, M. D., etc. 8vo.; pp. 688. Lea Brothers & Co., Philadelphia, 1887.

This work, which appears now in its second edition, is intended as a sort of guide book for the advanced student of medicine. It is not a manual of diagnosis, but a series of directions as to where the attention should be directed in the study of clinical cases.

It treats of such topics as: "The Physiognomy of Disease," "General Signs of Pyrexia," "Examinations of the Organs of Special Sense," "Electrical Instruments in Diagnosis," "Symptoms of Disorder of the Nervous System," "The Signs of Insanity," "Examination of the Urine," "Physical Examination of the Chest," etc. Contributions on these subjects are incorporated from half a dozen different physicians and surgeons, all members of the profession in Scotland. Although this involves a lack of continuity in the plan of the work, it contains a large amount of useful matter which cannot fail to be instructive in the cases for which it is intended.

The Annual Report of the Supervising Surgeon General of the Marine Hospital Service for the year 1886. 8vo., pp., 312. Washington.

Besides the usual merely official matter in this report, there are the details of the autopsies of a number of fatal cases, and clinical descriptions of various instances of rare diseases which had occurred during the year. At the close of the report there is given the translation of the conclusions adopted and propositions rejected by the technical commission of the International Sanitary Conference at Rome, in 1885.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

SIMPLE METHOD FOR REVIVING PERSONS APPARENTLY DEAD.

Various forms and kinds of apparent death have been described, but these distinctions refer mainly to the initial stages of such conditions, while the morbid state known as "apparent death," (Scheintodt) when completely developed, is always the same, being characterized by a weakness and paresis of the heart and by a stagnation of the circulation due to the latter. All methods, therefore, intended to resurrect such individuals, must be directed against the debility of the heart and against the impeded circulation; but thus far our aim in these cases has been mainly the maintainance of respiration, though the latter has probably to ascribe its effect only to its power of stimulating the heart to renewed activity.

At a meeting of the last congress of German scientists this subject was discussed, and Dr. H. Frank mentioned that there are but two ways to stimulate the heart: electricity, and mechanical concussion of the heart. The first is considered dangerous by him, as it may easily destroy the last power of contraction remaining in the organ; but what is termed "pectoral concussion," is decidedly preferable. F.'s method is as follows: He flexes the hands in the wrists to an obtuse angle, places them both near each other in the ileo-cæcal region, and makes vigorous strokes in the direction of the heart and of the diaphragm. These strokes are repeated from 15 to 20 times, and are succeeded by a pause, during which he strikes the chest over the heart repeatedly with the palm of his hand. In favorable cases this method is early successful, and sometimes a twitching of the lids or of the angles of the mouth appears with surprising rapidity as the first sign of returning life. As soon as these symptoms are noted, the simple manipulations above described must be earnestly continued, and persevered in for from a half to one hour, for with their cessation the phenomena indicating beginning return of life also cease. Generally the face soon assumes a slight reddish tint, and at the same time a faint pulsation may be felt in the carotids. By this method F. has seen life return in fourteen cases, amongst whom were such as had hung themselves, drowned, and asphyxiated by carbonic oxide, and in one case by croup. In three cases of asphyxia by coal gas, and in one case of apparent death by chloroform, the method described alone succeeded. F. advises, therefore, the practicing physician not to lose time with other procedures, but at once to employ a method which,

in his hands, has proved so universally successful.

In confirmation of the views expressed the following case may be quoted, which was reported by Dr. v. Bash. Electrity was applied to revive a drowned woman, apparently asphyxiated, but in whom various symptoms had proved life still to be there. Suddenly the patient became deadly pale, completely lost consciousness, white froth appeared at the mouth, and respiration and the pulse at the wrist ceased. By kneading energetically the abdominal walls, life was brought back. B. had been induced to practice this procedure by the results he obtained from experiments on animals. He had noticed that the passage of the blood into the intestines and other abdominal organs produces weakness of the heart; to this are probably due the sensation of fainting, so often observed immediately before vomiting in some gastric and intestinal disorders, and also the sensation of nausea, which often is the immediate precursor of a fainting-fit; while pressure on the abdominal walls produces fullness of blood in the heart and a revival of the activity of the latter. Electricity in such cases is very dangerous, as the last portion of life remaining in the main organ of circulation may become totally extinct by stimulating a heart empty of blood, and it is surprising to note that its application in fatal chloroform narcosis is still recommended, though reported as not preventing death in many cases.

THE STUDY OF VETERINARY MEDICINE.

A gratifying proof of the greater intelligence of the community is the higher position which veterinary medicine is gaining in general estimation. Within easy memory, and even yet in some parts of the country, the vocation of "horse-doctor" was looked upon with a certain contempt by the more intelligent of the community.

A change, however, is rapidly taking place. The establishment of first-class instruction, as that furnished at the University of Pennsylvania and at Columbia College, N. Y., will soon show the intelligent minds of our people that to understand the diseases of the lower animals requires just as hard study, just as profound attainments, as to master those belonging to the human species.

Our government has done good service in this respect through its publications on the diseases of domestic animals, and through the aid it has extended toward making thorough researches into the minute pathology and the etiology of the more destructive epidemics which have been so injurious to stock raisers.

These publications, and this branch in general, should not be overlooked by physicians, especially by those who practice in country localities. They should procure the principal issues of the Bureau of Agriculture, which they can easily do through the congressman from their district, and with the guidance of one or two text-books of veterinary anatomy and surgery they can readily place themselves in a position to treat with efficacy most of the curable diseases of stock. A potent incentive to this will be that thereby they can add a nea succedaneum to their annual income.

FUMIGATIONS WITH SULPHUR.

Many articles, as clothing, etc., could be disinfected only if it could be done with hot vapor, by gaseous substances, or by fumigation. Hot watery vapor, if of sufficient heat, is probably the best remedy, as the clothing does not lose its color, nor is it ruined otherwise; but the application in this manner of steam can only be employed in institutions where special arrangements have been made for it. What is needed is a method which may be used in any room. Chlorine, which has been strongly recommended, is dangerous to inhale, and besides its bleaching effect is not desirable. Sulphur could be best employed, but of late voices have been raised denying its effect. To determine the question, Dr. S. Schidlovski has made a series of observations (*Wratsch. Russ.*, 26, '87), with the following result:

300 grm. O. are needed to burn the same quantity of sulphur, but practically only one-third of the sulphur used in a well-closed box burns in such a manner as to be effective, a fact of importance in determining the amount of sulphur to be used in a given case. Various materials were infected with microbes of all kinds, and hung up in the nearly hermetically closed room where the sulphur was to be burned. Fumigation in this way, even if twice repeated, was generally without effect, but after the third fumigation the spores were killed. The interesting observation was also made that the articles which were hanging in the upper parts of the room were not so completely disinfected as those in the lower.

From these experiments the reader may himself draw the conclusions how fumigations with sulphur, to be effectual, should be used.

Notes and Comments.

Treatment of Diphtheria Before and After the Larynx is Involved.

Within the past two years Dr. John Irving (*Brit. Med. Jour.*) has had a large experience of epidemic as well as endemic diphtheria. Satisfactory recovery in fifty or sixty instances—all the latter cases laryngeally uncomplicated when he was sent for—makes him regard iron and carbolic acid as not only prophylactic, but specific. At first he employed liq. ferri perchlor. with glyc. acid. carbolici, adding a little acid. phosph. dil. for appearance' sake; but now he finds the following mixture to be equally efficacious, readily taken by children, for continuous use much better suited to the stomach, and more attractive to look at. For a child one year old, the prescription is;

℞.	Liq. ferri dialysati,	ʒss.
	Glyc. acid. carbolici pur. (P. B.),	ʒss.
	Glycerini pur.,	ʒss.
	Syrupi simplicis,	ʒiss.

Misce bene, adde aquam ad. ʒij.

Sig.—One teaspoonful to be given every two hours; and it is better to continue it eight days at least.

This mixture is useless if the larynx be involved.

A few weeks ago he was summoned to a case of laryngeal diphtheria in a girl aged 3 years. Her parents objected to tracheotomy. Under treatment as above, the breathing became worse, and at the end of twenty-four hours he gave

℞.	Potassii iodidi,	grs. v.
	Sol. nitro-glycer. (1 per c.),	♏iv.
	Vin. antimonialis,	♏xlviij.
	Glycerin. pur.,	ʒij.
	Aq. ad.,	ʒij.

M. Sig.—One teaspoonful every two hours.

Contrary to his prognosis, and contrary to his previous experience, the child gradually improved; the membrane loosened, and was coughed up in large pieces. She is now well, and recovering her voice by the help of Easton's syrup.

Rash Produced by Antipyrin.

Two cases have lately come under the notice of Dr. E. O. Dally (*Brit. Med. Jour.*), in which a rash closely resembling that seen in measles appeared in patients who were taking antipyrin. The rash observed differed from that of measles in the following points:

1. It did not make its first appearance on the forehead, was most marked on the extremities, though also present on the trunk, and to a limited extent on the face.

2. It was arranged in crescentic patches, and its color was rose-red.

3. There was an absence of general symptoms, for example, swelling of the face and eyelids, coryza, lachrymation, cough, etc.

4. Its duration was only from twenty-four to thirty hours, quickly subsiding after the drug was left off.

Probably those who use the drug much have noticed a similar eruption. It seems to cause no inconvenience, and would hardly be worth mentioning, were it not that from its resemblance to measles it might be mistaken for that disease, and so occasion the unnecessary isolation of the patient, and the fumigation of his clothes and room.

An Antidote for Arsenic and Aconite.

In a recent number of the *Indian Statesman* there appears a communication from Syed Walayet Ali Khan, of Patna, Bengal, on a specific antidote for poisoning by arsenic and aconite. It is described as being the bark of the common goolar tree, generally known to Europeans as the Indian fig. It is administered in doses of from ten to twelve drachms, ground fine, and mixed with water. In severe cases it may be necessary to repeat it at short intervals three or four times, but it is said never to fail. It has been found successful, according to the author of this statement, in every case in which it has been tried. We have consulted Dymock's "Vegetable Materia Medica of Western India," Waring's "Bibliotheca Therapeutica," and other works, but can find no reference to its use for this purpose. It seems strange that it should be an antidote both for arsenic and aconite, as these drugs do not produce the same symptoms, and are not allied physiologically. The matter requires further investigation, and we must admit that we are at present skeptical as to its value.

Myoctonine.

The *Journal de Médecine de Paris* publishes the following note on myoctonine: Myoctonine is one of the two substances extracted from aconitum lycoctonum by MM. Dragendorff and Spohn. It is a yellow, bitter, amorphous body, having for its formula C_{27} H_{30} N_2O_8, and fusible at a temperature of from 143.5° to 144° C. It is not very soluble in water, but much more so in acidulated water, and soluble in all proportions in sulphide of carbon, absolute alcohol,

chloroform, and benzine. Ether and the light essence of petroleum only dissolve traces of it. Myoctonine is a powerful poison, resembling curare in its action. The injection of $\frac{7.5}{1000}$ of a gramme produced distinct toxic symptoms in a cat, while one-tenth of a gramme caused death in twenty or thirty minutes. Lycoctonine and lycaconine, which are products of the decomposition of lycaconitine and of myoctonine, have a physiological action which recalls that of the primitive alkaloids, but less powerful.

The Value of Indian Hemp in the Treatment of a Certain Type of Headache.

The headache which Dr. Stephen Mackenzie describes in the *Brit. Med. Jour.* is of a dull, continuous, or subcontinuous character, attended sometimes with paroxysmal exacerbations. What is especially characteristic of it is its constancy. Patients will tell you that they rise with it in the morning, are troubled with it all day, and carry it to bed with them at night. If by chance they awake in the night, they find their head is aching. The headache may, in some cases, become aggravated as the day advances, but sometimes the opposite condition obtains, and the headache is worse at the early part of the day. The situation of the headache varies; it may be frontal, temporal, or occipital, or, more rarely, vertical. Usually, however, it is diffused. In such cases he has had good results from the use of fluid extract of Indian hemp in doses of one-third grain, or more, night and morning, or thrice daily, increasing or diminishing the dose as required.

Treatment of Chronic Tropical Diarrhœa.

Pepsin has been found very valuable in these cases by Dr. G. Harrison Younge, who records his experience in the *Medical Press* for January 12. Care should be taken that the pepsin is fresh, as otherwise it is almost useless. Only milk diet should be allowed, and in preparing it care should be taken that the temperature is not raised above 100°, as if it is the action of the pepsin is destroyed. In mild cases the pepsin may be given in powder after meals, while in severe cases half a pint of milk was given every third hour. The temperature of the milk was raised to 100°, and to each half pint was added 5 gr. of pepsin. It was allowed to stand for half an hour, the temperature being maintained at 100°. It was then given to the patient. At the same time all medicines were stopped. The return to full diet should be gradual, and the pepsin should be continued for some time after all diarrhœa has ceased.

Plugging the Anterior Nares.

There is often considerable difficulty in getting a string from the anterior nares round by the pharynx and out at the mouth, preparatory to performing this operation; and various appliances have been devised for the purpose. For several years Dr. Bryson (*Brit. Med. Jour.*) has always resorted to the following method, and found it both easy of application, efficient, and handy, as the apparatus is always obtainable: Take a piece of twine of sufficient length, and fasten to the end of it a pledget of lint or rag, the size of a large pea, or a small globular button with a neck does very well. Then form a ring about a quarter of an inch in diameter, on the small end of a silver probe or piece of wire, and bend it down. Run the twine through the ring till the pledget or button is close against it. Then pass the wire or probe along the floor of the nose; tell the patient to hawk, and spit out, and at once the pledget with the twine attached is ejected.

Resorcin in Acuminated Warts.

In the *Russkaia Meditzina*, No. 38, 1886, Dr. G. J. Gatchkovsky, of Rybinsk, states that he most successfully treated thirty-four cases of acuminated condylomata by powdering with pure resorcin. He details an interesting case of a young man, aged 17, who never had gonorrhœa or syphilis, but suffered from moderate balanitis, and in whom in course of time there developed two large condylomata (one of the size of a little finger, another of that of a raspberry), and thirty smaller warty excrescences, varying in their size from a hemp-seed to a big pea. Before coming under Dr. Gatchkovsky's observation (about six months after the appearance of the first new growths), the patient remained without any treatment whatever. The small warts disappeared completely after four days' treatment with resorcin; the large condylomata dwindled away three or four days later. No recidive followed.

Case of Hard Chancre of the Vagina.

The following case, observed by Dr. Max Bockhart, is worthy of note on account of the seat of the lesion (the vaginal wall being a very rare locality for primary venereal sores); also on account of the well-marked

induration and the mode of contagion. The patient was a young woman, aged 20, who had had intercourse with her lover, who was suffering from numerous mucous papules on the penis. On examining the woman, Dr. Bockhart found a clearly indurated sore on the posterior vaginal wall. It appeared that the man, in order to increase the sexual enjoyment of his paramour, had made use of a peculiar kind of capote (*Reizcondom*) furnished with three rows of conical projections. By this means excoriation of the vaginal surface was produced, and then, in a subsequent coitus without the condom, contagion was supposed to have taken place. Symptoms of secondary syphilis appeared in the woman in due course.

Indurated Chancre of the Elbow.

The patient in this case, a man aged 26, did not come under M. Fournier's observation at the Hôpital Saint Louis until general signs of syphilis were already well developed, and probably about four months after contagion. Besides a general syphilide and lesions of the throat, etc., there was a healing sore with indurated base over the right olecranon, and well-marked indolent enlargement of the corresponding axillary glands. The inguinal glands were not enlarged. On the genital organs were some of the papules of the general eruption, but no trace of any primary sore. The history the man gave was that he grazed his elbow about four months previously, and that sores formed there about three weeks afterwards. He had had sexual intercourse with public women while the elbow was still sore. M. Fournier, though he had seen primary sores on almost every part of the body, had never before seen one on the elbow.

Case of Acute Multiple Gangrene of the Skin.

Doutrelepont (*Viertelj. für Derm. u. Syph.*, 1886, Heft 2,) gives a detailed account of an interesting case of this rare disease. Rounded, gray-white plâques, with a pricking, painful sensation, with or without preceding hyperæmia of the skin, show on their surface a certain number of rounded spots of a yellowish color. The patch, therefore, seems to consist of small rounded efflorescences; there is no swelling in the plâques nor pustules, and the skin remains flat. Soon after the plâque, the line of demarcation is formed, which is surrounded by a hyperæmic border; the gangrenous portion of the skin acquires a greenish-yellow color, becomes detached, and the surface slowly heals. The gangrene was limited to the cutis. Before treatment, most of the scars became keloid. Dressings of one per cent. bichloride solution seemed to prevent the keloid formation.

The Use of the Electric Endoscope.

An account is given by Dittel (*Centralb. f. Chir.*, 1886,) of the applications of this instrument for the better diagnosis of special forms of cystitis, hypertrophy of the prostate, new growths, and foreign bodies in the bladder. The apparatus which he employs is that invented by Nitze. In most cases the instrument is introduced by the urethra, but in the case of an enlarged prostate, a supra-pubic opening should, he suggests, be made if it is necessary. At the same time he draws attention to the fact that without some practice one is liable to mistake, or to misinterpret the appearances which are presented to one's vision. Thus he cites an instance in which an old case of cystitis with great thickening of the bladder walls was mistaken for a carcinoma. The price of the instrument, from $50 to $75, is also a bar to its general adoption.

Intestinal Displacement a Cause of Dyspepsia.

M. Glénard, a Vichy physician, believing that displacements of the intestine or "enteroptoses" are a good deal more frequent than is generally supposed, and that they are, indeed, a common cause of dyspepsia, has been in the habit of examining the dyspeptic and neurotic patients who consult him by making them stand up, and then going behind them and pressing on the abdominal wall when in a relaxed condition. If this produces a distinct alleviation of the discomfort he considers that enteroptosis is present, and orders a binder, which in these cases gives great relief, only lasting, however, while it is actually worn. A discussion on this subject has just taken place at a meeting of a Paris medical society, but M. Glénard did not find many of his colleagues prepared to accept his views.

Boldo-Glucine in Nervous Insomnia.

Dr. René Juranville has been studying the hypnotic action of a glucoside extracted from the leaves of the Chilian plant, boldo (*pneumus boldus*). M. Chapoteaut, who discovered this body, has called it boldo-glucine. After trying experiments on dogs, which appeared to show that boldo-glucine was a safe

hypnotic, producing a certain degree of cerebral anæmia, Dr. Juranville administered it either per rectum or in capsules, in doses of 1.5 to 5 or even 8 grammes, to a number of patients suffering from different forms of insanity with insomnia. All the patients obtained sleep, or, at least, rest from excitement, and some were relieved from nocturnal hallucinations. Though the effect of the drug was, however, only temporary, the author believes it will prove useful in many cases of nervous insomnia, when other remedies have been unsuccessful.

The Etiology of Epidemic Scurvy.

In the *Sbornik Permskaho Zemstva*, No. 2, 1886, Dr. J. J. Molleson, of Perm, publishes a valuable paper on two epidemics of scurvy which raged over the Perm Government in 1884 and 1885, attacking in the former year 3,062 persons, and in the latter 4,450. Basing his statements on the statistics collected by local practitioners, he shows that scurvy represents mainly a result of a bad food supply. The author's tables most convincingly establish an invariable striking co-relation between the numbers of scurvy patients and bad harvests of corn and potato. Those districts (*üüezdy*) which most severely suffered from bad crops in 1883 and 1884 presented also the greatest numbers of scurvy cases in 1884 and 1885 respectively. The less unfortunate parts of the Government showed correspondingly lesser numbers of scurvy cases.

The Treatment of Lupus by Topical Applications of Bacterium Termo.

Dr. Viñeta-Bellaserra, inspired by the attempts of Cantani and others in the treatment of pulmonary and laryngeal tuberculosis, has tried this plan in lupus, which is now recognized by the majority of dermatologists as a local tuberculosis. He first scarifies the lupus with Vidal's instrument, and then applies cotton-wool soaked in the liquid of a germ-cultivation of the bacterium termo, covering this with gutta-percha, and maintaining it in contact with simple strapping. The application is renewed every twenty-four hours, the scarifications every two days. His results will be published shortly.

Transplantation of the Cornea with Preservation of its Transparency.

Von Hippel, of Giessen, recorded at the last meeting of the German Ophthalmological Society, a case of transplantation of the cornea in which the membrane had preserved its transparency for a considerable period. In general it becomes opaque in the course of two or three weeks, even when perfect union has taken place. Helmholtz believes that the opacity results from the aqueous humor coming into contact with the corneal tissue proper, in consequence of injury to the membrane of Descemet. M. Hippel avoided this by removing only that portion of the cornea which lies in front of the membrane of Descemet. In his case the vision was six-sixtieths eight months after the transplantation had been effected, the cornea still remaining clear.

Complete Cure of Chronic Peritonitis by Drainage.

Beljaeff records the case of a woman, aged 32 (*Centralbl. f. Chir.*, 1886,) who became the subject of chronic peritonitis as the result of an abortion, followed by endometritis and perimetritis. A considerable amount of ascites ensued, and the abdomen was twice tapped. As this did not in any way benefit the patient except for a time, it was decided to open the abdomen. At the time of the operation both the parietal and visceral layers of the peritoneum were much thickened and more vascular than natural. The fluid contained a small amount of fibrin, and blood corpuscles. The peritoneal cavity was thoroughly rinsed out with a $\frac{1}{30}$ per cent. sublimate solution, and drainage was effected per vaginam from Douglas's pouch. After three months' drainage a complete cure was the result.

The Operative Treatment of Paralytic Equinovarus.

At the meeting of the General Surgical Congress at Berlin, Rydygier, of Kulm, introduced a new mode of treating this affection. He opens the ankle-joint, and after scraping the surface of the bones puts it up again in a firm apparatus, and allows it to ankylose. By this means the flail-like condition of the foot is obviated. A somewhat similar operation was performed by Von Lesser several years back, the only difference being that he made a lateral incision, so as to get fore-drainage and not anterior, as is at present proposed by Rydygier. The advantage of such an operation is clearly shown by the result of Lesser's cases, which at the present time are well and healthy, and able to walk on their feet, which were before perfectly useless to them.

Neisser's Gonococcus in Gonorrhœal Arthritis.

In the *Vratch*, No. 31, 1886, Dr. P. V. Smirnoff, of Prof. N. M. Lubimoff's laboratory in Kazan, writes that he has examined a sero-purulent fluid aspirated by Prof. N. P. Studensky from the inflamed right knee-joint in a patient aged 28, in whom arthritis had developed about a month after his contracting gonorrhœa, and twenty-six days after the appearance of orchitis. Numerous groups of Neisser's microbes were found within pus-cells. Hence the author comes to the same conclusion to which Petrone, Kemmerer, and M. I. Afanasieff (who also found gonococci in inflamed joints in gonorrhœal arthritis) arrived; that is, that the articular inflammation is caused by Neisser's gonococcus entering the blood.

Pemphigus Vegetans.

Under this name, Neumann (*Viertelj. für Derm. u. Syph.*, 1886, Heft 2,) describes an affection which coincides with the framboesia syphilitica of Kaposi. He considers that it is associated with syphilis. The course of pemphigus vegetans is acute, and the eruption reveals itself on the skin of the genitals and the inner surface of the thigh, armpits, and the mucous membrane of the month; later on the whole surface of the skin. The mucous membrane of the pharynx, larynx, vulva, and also of the vagina, is affected; the anal folds are scarcely ever free. The nodular condylomatous growth continues to appear until the patient dies.

Incontinence of Urine After Labor.

Real incontinence of urine consequent on labor is a rare phenomenon, except as the result of urinary fistulæ. It is due to lesions resulting from pressure on and bruising of the urethra by the fœtal head when the latter has remained for some time pressing against the pubic arch, or when the pressure in passing has been severe. It is not a functional disorder, since it is often due to genuine anatomical lesions. A cure often takes place spontaneously. Electricity, judiciously employed, is sometimes of service, and should always be tried in cases where no evidence of injury to the urinary passages is present.

Pulsatilla in Acute Orchitis.

Having witnessed the striking curative action of pulsatilla in acute orchitis and epididymitis, Dr. Gerard Smith would like to persuade others to follow Dr. Brunton's advice, and give this drug in inflammatory states of the testicle, epididymis, and spermatic cord. To have it in our power to subdue promptly the intense suffering of such cases, is a great blessing; and the relief is so rapid that it is even unnecessary to employ morphine to subdue the pain, whilst the swelling and heat subside more rapidly than under any other drug.

Contagious Pneumonia.

In the *Canadian Practitioner*, November, 1886, Dr. J. E. Graham describes a series of cases of pneumonia which he has recently observed. From a study of these cases, as well as the literature of the subject, he is led to draw the following conclusions:

1. That lobar pneumonia is in almost if not in all cases an essential fever.
2. That it is a parasitic disease.
3. That it frequently occurs in the form of epidemics.
4. That it occasionally has appeared to be contagious.
5. That the disease, in an epidemic or contagious form, is nearly allied to erysipelas.
6. That the early and persistent administration of tincture of iron is the proper treatment for these cases.

Nitro-Glycerine in Suspended Animation.

An interesting case is reported in the *Sei-i kwai* medical journal of Japan for November, of the resuscitation of a woman apparently dead by the hypodermic injection of nitro-glycerine. It was a case of collapse after child-birth. Dr. Sackersteen injected ten drops of a solution of nitro-glycerine (strength not given) into a vein. She made a good recovery. It has been suggested that this drug be used in cases of overdoses of chloroform and shock from surgical operation.

Cocaine in Whooping-cough.

Repeated painting of the throat with a 5 per cent. solution of cocaine is stated by Dr. Lahric to have caused an immediate lessening in the number of attacks, children having fifteen or twenty attacks in the twenty-four hours only having five to ten attacks after the application. As the topical effect of the drug is of short duration, it is necessary to repeat it fairly often, but no tolerance is established, as with other drugs. Improvement took place in the general health, probably due to the diminution in the cough.

Syphilitic Infection through Trousers.

In the *Vratch*, No. 26, 1885, Dr. P. P. Glagoleff, of Saksky Military Mud Baths, reports the case of a soldier, aged 23, in whom, two weeks after he had been in hired trousers at a masked ball, there appeared three hard, almost painless ulcers, situated a little below the inguinal fold. Four weeks later, roseolæ, anal condylomata, and mucous patches, made their appearance. The suspected trousers were so tight that the patient was obliged to put them on without drawers.

Antifebrine.

Professor Gerhardt has employed this remedy in ten cases of articular rheumatism, in doses of 3 grammes three times a day. In five of the cases (not recent) it was of no service. In five others (quite recent) it cut the disease short in one case, in two others it was almost completely successful, and in the two last its action was only moderately so. He likens the action of the new drug to that of antipyrine, to which it has, however, no relation chemically.

Chalk Ointment in Erysipelas.

Either precipitated or prepared chalk and previously melted lard, equal parts of each, to each one ounce of which ointment half a drachm of pure carbolic acid is added, is recommended by Dr. Dyce Duckworth in the *Practitioner* as a local application in erysipelas. This preparation is now the favorite one in the erysipelas wards at St. Bartholomew's Hospital.

Correspondence.

Lake Fevers.

Eds. Med. and Surg. Reporter:

In Turner's "History of the Holland Purchase," I find a theory of the causation of "lake fevers," which reminds one of the modern germ theory of disease.

De La Barre, Governor General of New France, in 1684, massed all his available troops at Fort Frontenac, in the month of August. The soldiers, not being inured to the climate, were attacked by "lake fever." La Hontau, quoted by Turner, loc. cit., p. 137, gives the following as the theory De La Barre's physician advanced concerning the febrile invasion:

"It was that the excessive heat of the season put the vapors or exhalations into an over-rapid motion; that the air was so over-rarefied that a sufficient quantity of it was not taken in; that the small quantity taken in was loaded with *insects* and *impure corpusculums* which the fatal necessity of respiration obliged the victim to swallow; and that by this means nature was put into disorder."

Impure corpusculums have been supplanted by swarms of pathogenic bacteria. The "fatal necessity" of respiration—*besoin de respirer*—still exists. Nature, in 1684, as Baron La Hontau observes, was put into disorder by the impure corpusculums and the "Iroquois strain." The breezes of the present are laden with bacilli. Microzymes are now aided by "business strain"—the general prostration and nerve exhaustion of over-work.

Lyndonville, N. Y.

Unique Penis Syringe.

Eds. Med. and Surg. Reporter:

I send you a description of the following little device, which I have dubbed "Unique Penis Syringe," to be used in lieu of the common penis syringes. It consists of a glass tube or barrel three and a half or four inches in length, one-half an inch in diameter, conical at one end to fit the meatus urinarius, and to the end is attached a hollow rubber ball an inch or more in diameter. By compression and expansion of the ball, fluid can be drawn up and forced into the urethra and returned to the syringe, thus perfectly washing the urethra, the desideratum in urethral injections.

A word as to directions: After the syringe is partly filled, the conical end is snugly fitted to the meatus, and by raising and compressing the ball, the fluid is forced into the urethra; then lower the ball and let it expand, and the fluid is again returned to the syringe. By this maneuvre the injection can be changed and a complete cleansing of the urethra effected. With the barrel of a common glass syringe and a small rubber ball, I made a very good instrument.

Bellaire, Ohio.

The Alkaline Antiseptic Treatment of Gonorrhœa.

Eds. Med. and Surg. Reporter:

Apropos to the new alkaline antiseptic treatment of gonorrhœa: About a year ago, reasoning from the parasitic theory, I treated a recent case of gonorrhœa with frequent

thorough injections of a ten-grain solution of sulphite of soda in water. We secured a complete cure in ten days from the beginning of treatment. It was the patient's first case, and he was a robust, hearty man of 24 years, and kept at work driving team. There was no doubt of the genuineness of the case. One of his companions, who contracted it from the same woman about the same time, came to me two months afterward for treatment. His discharge had been gleety for some time, but had taken on an exacerbation, and was again purulent. The soda sulphite solution quickly reduced it to gleet again, but it required astringents to complete the cure. I have had no experience with the disease since.

Allegheny City, Pa.

Cocaine and Dobell's Solution.

Eds. Med. and Surg. Reporter:

I wish to call the attention of the profession to the fact that cocaine and "Dobell's solution" are incompatible, and a precipitate is formed because the alkalies are so potent in this solution.

Jno. A. Robison, M. D.

Chicago, Ill.

News and Miscellany.

Foreign University Intelligence.

Lyons.—M. Berne, professor of external pathology, has been obliged by ill health to obtain leave of absence during the present academical year.

Paris.—The candidates for the Chair of Internal Pathology, vacated by M. Peter, on his appointment to the Professorship of Clinical Medicine at the Hôpital Necker, were MM. Debove, Dieulafoy, Duguet, Joffroy, Lancereaux, Landouzy, Quinquand, and Strauss. From these the faculty was selected: (1st) M. Dieulafoy, (2d) M. Strauss, and (3) M. Duguet. The selections for the Professorship of Anatomy are (1st) M. Farabeuf and (2d) M. Rémy; and those for the Chair of Physics are (1st) M. Gariel and (2d) M. Desplats. A new professorship, the chair of which will be filled by Dr. Dubuisson, is about to be established at the School of Law. He will treat of "Mental Maladies" from the point of view of the legal responsibility of criminals affected in their mind.

St. Petersburg.—Prof. Sorokin's term of office has been prolonged for a period of five years.

Odessa.—After a good deal of delay or uncertainty about the establishment of a medical faculty, the Town Council has decided to grant the sum of £900, which is required to enable the university architect to visit and inspect foreign buildings of a similar nature, and to prepare the plans, on the express condition, however, that the Russian Government will promise definitely to authorize the establishment of the proposed medical faculty.

Olfactory Acuteness.

An interesting contribution, says the *Med. Press*, was recently made by Messrs. Nicholls and Bailey to *Nature*, giving the results of experiments upon the relative acuteness of the sense of smell in individuals. A series of solutions of oil of cloves, nitrite of amyl, extract of garlic, bromine, and prussic acid were prepared by successive dilutions with water until the limit of perception was reached, and then the solutions were placed indiscriminately and submitted to a number of persons of both sexes to classify them properly by the sense of smell. The results showed that on the average the sense of smell was much more delicate in the males tested than in the females; but the degrees of keenness ranged widely as between individuals. Thus three male observers were able to detect one part of prussic acid in 2,000,000 parts of water, though its presence was not revealed by a chemical test; but others, of both sexes, could not detect prussic acid in solutions of almost overpowering strength. The following figures give the average limit of delicacy of perception:

Cloves.—Males, 1 in 88,128; females, 1 in 50,667.

Nitrite of Amyl.—Males, 1 in 783,870; females, 1 in 311,330.

Extract of Garlic.—Males, 1 in 57,927; females, 1 in 43,900.

Bromine.—Males, 1 in 49,254; females, 1 in 16,244.

Prussic Acid.—Males, 1 in 112,000; females, 1 in 18,000.

The Phylloxera.

The average yield of the French vintage for the four years from 1875 to 1878, inclusive, was 1,275,000,000 gallons. The last three vintages have decreased at a greater rate than 100,000,000 gallons per year, and now it is reported that in the vintage of 1886 more than one-fifth of the yield was produced

from dry raisins and dregs of the first and second press. Although it is beginning to be the fashion to ascribe this decrease chiefly to mildew and other causes, the presence of the phylloxera must be regarded as one of its principal causes. After a variety of researches only one method has been found to effectually kill this insect, and that is by inundation, begun in November and continued for forty days. The vineyard on which this experiment was tried was one of the first to be attacked. In 1867 the wine produced was 925 hectolitres; in 1868, 40; in 1869, 85; in 1870, the first year of submersion, 120 hectolitres. Since that year the quantity produced has gradually increased, until it has nearly reached its normal figures, and the vines have regained their vigor. The commission appointed in France, which publish every year such a heavy report, have chiefly studied methods for killing the insect underground, and but little practical benefit has attended their action. Had they directed their energies to a policy of extermination above ground, very different results might have been attained.

Capital Punishment by Electricity.

The horrid features of capital punishment by hanging (says the *N. Y. Med. Jour.*)—a term tantamount in the majority of instances to strangling—have often received consideration from a medical point of view. It is now announced that a legislative commission appointed to inquire into the merits of various devices for putting murderers to death with less repulsiveness will shortly report to our State Legislature in favor of the adoption of electricity. It is thought that the result is likely to be the passage of a bill abolishing execution by the gallows. A medical member of the commission is said to have expressed the wish that this State would "take the initiative in this step toward a broad humanity," and to have professed his gratification that France, Germany, and New Jersey seem to have had their serious attention turned to the matter in consequence of the New York inquiry.

A Doctor Who Could Shoot.

The *Indiana Medical Journal* is responsible for the following: During the twenty years which Dr. Ackley practiced in northern Ohio his reputation became very great. He was a man who was impulsive in his actions, as is shown by the following incident: One day while out duck-shooting he was accompanied by a favorite dog. Another hunter was on the opposite side of the stream, and as the ducks which he shot fell into the water, Dr. Ackley's dog would swim in and get them. The man objected to this, but Ackley told the man he should have all the ducks retrieved by the dog. The man answered that should the dog retrieve another duck he would shoot him. Ackley replied if the man shot the dog he would shoot the man. Another duck was shot and in sprang the dog, and was as promptly shot. Ackley reciprocated by filling the man full of shot from his fowling-piece, after which he immediately left the scene and returned rapidly to the city. Some time later a man came into his office complaining that some one had filled him full of bird-shot. Ackley proceeded to pick them out one by one, at the same time condoling with the man, and at the close of the process charged him a good bill.

A Sign of Death.

Among the means of determining between actual and apparent death, M. Peyraud regards cauterization of the skin by Vienna paste as one of the most certain. In the living subject the eschar formed will be of a reddish-black or brownish color, while in the cadaver it is yellow and transparent. If the eschar is formed slowly and is of a yellow color, the subject is dead, but if it is red, brown, or black, it may be assumed that life is not yet extinct.

The Use of Cocoa.

The total consumption of cocoa is 80,000,000 pounds per annum, supplied mainly by the West Indies and South America. France heads the list with with 26,000,000 pounds; Spain comes next with 16,000,000 pounds; then follows England, 14,000,000 pounds; and the United States, 8,500,000 pounds. In this last country the use of cocoa has increased more than six-fold since 1860, while that of tea and coffee within the same period has not quite doubled.

The Harvard Medical School.

In the recent annual report, the President of Harvard University spoke as follows of the medical department: "The medical school makes a slow gain in the number of students and its annual income, but is nevertheless doing excellent work. A plan for abridging the four years' course of study in certain cases is now under consideration."

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE SIX WEEKS ENDED JANUARY 29, 1887.

Wyman, Walter, surgeon. Granted leave of absence for three days, January 14, 1887.

Wheeler, W. A., passed assistant surgeon. To proceed to Erie, Pennsylvania, as inspector, January 12, 1887.

Personal.

—Dr. William Stevenson Robertson died at his birth-place, Muscatine, Iowa, on January 20, aged fifty-six years. He was President of the Iowa State Board of Health, and Professor of the Theory and Practice of Medicine in the Iowa State University.

Items.

—The mortality from labor in China is estimated to be eight per cent., or about four hundred thousand deaths annually.

—The *Pennsylvanian*, published by the students of the University of Pennsylvania, is to contain a series of short sketches of University professors, the first of which will appear in a few weeks.

—The Scientific Society of the University of Pennsylvania has established a book exchange for the benefit of students. Second-hand books will be bought and sold, saving purchasers any needless expense.

—To investigate the existence of diseased bones, Dr. M. J. Roberts, of New York, drills a hole in the bone, and then introduces a small incandescent lamp of half-candle power into the opening, and thus illuminates the cavity.

—The Municipal Council of Bordeaux has decided that the name of Paul Bert shall be given to a street in Bordeaux. Paul Bert was one of the promoters of the Faculté de Médecine of Bordeaux, where he subsequently occupied a chair.

—The Faculty of Medicine of Paris has conferred the Lacaze Prize of 10,000 francs, awarded every four years for the best work on the treatment of fevers, typhoid in particular, to M. Albert Robin, for his "Leçons de Clinique et de Thérapeutique Médicales."

—The peculiarity of malarial disease in China, according to the Hospital Report of the American Episcopal Mission, is that there is a remarkable predominance of the quartan type, and the paroxysms are most likely to come on at night or in the afternoon.

—For the relief of the violent pains that in some women precede the menstrual flow, Dr. Meniere, of Paris, gives a warm water enema, containing thirty grains of chloral and thirty grains of bromide of potassium. For young women only half of the above quantities should be prescribed.

—During the progress of a fire recently in New York, Superintendent Frederick Simmons, who attempted to cut a wire of the United States Illuminating Company, which caused obstruction to the firemen, was instantly struck dead by the force of the electric current with which it was charged.

—The publication of the third medical volume, the last of the series comprising the *Medical and Surgical History of the War*, has been delayed by the pressure of current work at the Government Printing Office. The completed manuscript was ready for the press in February last, but scarcely a fourth of it is yet in type.

—A Virginia gentleman, incensed with a schoolmaster for flogging his son, drew a check in payment of the tuition fees due, and made it so insulting in its terms that the schoolmaster had it cashed and then sued the drawer for libel in "publishing" it, but he was defeated in the courts and was afterwards horsewhipped by his antagonist.

—At a recent meeting of the Paris *Société de Biologie* M. Féré said that he had lately observed an ataxic patient who had crises of profuse sweating or salivation, accompanied with fulgurant circumorbital pains and a unilateral increase of the lachrymal secretion, a phenomenon which, the speaker remarked, had already been noticed by Duchenne and Pierret.

—Dr. W. M. Lively, of New York city, on January 20, sent to the Bureau of Vital Statistics the certificate of death of Alice Downs, a colored woman, whose age he states to be 110 years, 11 months, and 9 days. She was born in Maryland, had never married, and had lived in New York for fifty-two years. The cause of death was pneumonia.

—Lady Visitor: "Well, how are you this morning, my dear?"

Invalid: "Oh, very low, indeed."

"Have you seen a physician?"

"Yes."

"What did he say?"

"That the malady was normal."

"And who is this doctor?"

"It is Dr. X."

"Ah, well, he was right; with him all maladies are normal."

Pallas Syringe."

[From the *London Medical Record.*]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Our New Lens Front, or Magnifying **Clinical Thermometers, with Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten aces. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,

CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of rec tations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

Lecture.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY WILLIAM GOODELL, M. D.,

Professor of Gynecology.

Reported by William H. Morrison, M. D.

INCONTINENCE OF URINE APPARENTLY DUE TO DISPLACEMENT OF THE URETHRA THE RESULT OF LACERATION OF THE PERINEUM—SOME GENERAL REMARKS ON LACERATION OF THE PERINEUM—MENORRHAGIA DUE TO THE PRESENCE OF FUNGOUS VEGETATIONS.

Gentlemen: The first case that I bring before you is one of partial incontinence of urine. Whenever you have a woman complaining of partial incontinence of urine, always pass the catheter. This is a golden rule that should always be borne in mind. When a patient presents herself with such a statement, the inference of many physicians would be that the bladder is empty, whereas it may be that there is incontinence of urine because the bladder is full. A woman may be two or three months pregnant when from some reason the womb becomes retroverted, or it may be that the retroversion was present before impregnation occurred. In either case the cervix presses against the neck of the bladder, and the woman is unable to pass the water which gradually accumulates in the bladder. After the bladder has become over-distended, and not till then, the urine will begin to dribble away. Again, a woman pregnant three or four months may take a long ride in a stage-coach or on a railroad, and may, through delicacy, neglect to empty her bladder. As she alights from the carriage, she makes a misstep which gives a little succussion to the womb, by which the fundus is forced behind the promontory of the sacrum and caught there. This displacement presses the cervix against the neck of the bladder, and the lady finds that, however urgent the desire, she cannot pass her water. In either case, an examination would in all probability disclose a cystic swelling above the pubes, which will disappear on the introduction of the catheter. I had quite a remarkable case of this kind some years ago. I was called by a physician to see a patient with stillicidium urinæ. She was three or four months advanced in pregnancy. Examination at once revealed an abdominal tumor, which closely resembled an ovarian cyst. I tried to pass a catheter, but I could not get it into the bladder. Finding that the womb was retroverted, with the cervix pressing very firmly against the neck of the bladder, I caught the neck of the womb with the volsella forceps and pulled the cervix down. Then with two fingers in the rectum I pushed the fundus up. This replaced the womb, and I now was able to pass the catheter. The urine filled the largest chamber-pot that I had ever seen, and a second vessel was required.

But our patient of to-day comes with another form of partial incontinence, and we must try to determine its cause. She is a married woman, and has had nine children. The one next to the last was delivered with instruments. The last labor was a breech presentation. This occurred fifteen months ago, and since then there has been a

constant dribbling of urine day and night. It is not always easy to determine the exact cause of this condition. There is here no vesico-vaginal fistula. Sometimes the condition is due to a dislocation of the urethra from the passage of the child during labor. Sometimes it is owing to the formation of a pouch in the urethra or urethrocele, as a result of some injury during labor. You will remember that a few weeks ago I brought before you a patient suffering with the same trouble that this woman presents. She had a bad tear of the perineum, going through the sphincter, with a great deal of cicatricial contraction. The parts were thus distorted, and the urethra had been displaced. I operated on the perineum three weeks ago, taking good care to bring the ends of the severed sphincter in apposition. The union has been good, and since the operation she has had much better control over the bladder, being able to hold her water for several hours. Incontinence of urine after labor is not at all uncommon, but it usually soon passes away. On the other hand, many young girls have a partial incontinence of urine, so that when they laugh or cough a few drops of urine escape. This infirmity usually depends on lax fibre, and then is to be treated by ferruginous tonics; but sometimes it is not readily cured, because anæmia is often not very easily controlled.

There seems in this case to be some dislocation of the urethra, or some injury to the muscular fibres of the urethra, for when she strains or coughs there is a gush of urine from the meatus. There has been a bad tear of the perineum, with prolapse of the anterior wall of the vagina. Hence I think that the best plan of treatment will be to restore the perineum so as to give the needed support to the urethra. Before resorting to operative measures, let us try the effect of the following prescription:

R.	Extracti ergotæ, fld.,	gtt. xx.
	Tinct. nucis vomicæ,	gtt. xv.
	Tinct. belladonnæ,	gtt. x.

Sig.—To be taken three times a day on an empty stomach.

This mixture often serves a useful purpose in girls as well who are troubled with incontinence of urine. In anemic cases the tincture of the chloride of iron may also be given along with the mixture.

I wish next to show you the result of the operation on the perineum in the case to which I have already referred, the woman with incontinence of urine. The union is good throughout nearly the whole extent of the wound. It would have been better could I have avoided the constant dribbling of urine over the wound. I at first introduced a self-retaining catheter, but the urine made its way along the sides of the instrument, and it was, therefore, removed. As I have stated, she has much better control over the urine than she had before the operation. The only way that I can explain it is that the new perineum has pushed up the urethra, which was displaced downwards during labor. Still we are constantly meeting with cases in which there is urethrocele, and in which the bladder is plainly prolapsed, and yet incontinence of urine is not present. The effect of the operation seems to indicate that the trouble was due to displacement. In order to stimulate granulation in the places where healing is not perfect, I shall have a solution of five or ten grains of chloral in an ounce of water applied.

GENERAL REMARKS ON LACERATION OF THE PERINEUM.

The next case is also one showing the result of operation in a case of ruptured perineum. One of the secrets of success in plastic surgery is to take your time in operating. This patient was operated on two weeks ago. She is a married woman who has had three children. The first was born naturally, while with the second and third the labors were instrumental. As a result, she came to us with a bad tear of the cervix, and with a tear of the perineum extending into the rectum. In nine out of ten cases, bad tears are caused in instrumental labors. This is not because the forceps were put on early to bring the head down on the perineum, but because the physician ended the labor with the forceps. There is not one physician in fifty who is capable of delivering the head with the forceps through the soft parts. In primiparæ I do not consider myself capable of doing it, although my experience has been great. I should do it only when, as in puerperal convulsions, it is necessary to end the labor at once. My advice to you is to put the forceps on boldly when their use is called for, and bring the head through the bony pelvis down to the perineum; keep the forceps on until the perineum begins to bulge and looks as though it were going to tear. Then let the forceps rest loosely in your hands, and observe the effect of the unassisted pains. If nature appears able to complete delivery, remove the forceps, and then if a tear occurs it will, in the majority of cases, not involve the sphincter. Almost all the bad tears of the cervix and of the perineum oc-

cur, as I have told you over and over again, in instrumental labors.

This case brought up the question of the advisability of operating on the cervix and on the perineum at the same time. Performing both operations at one sitting saves time.

The objection is that you perform two operations of some severity, and you have two wounds to heal. Some years ago I lost a patient on whom I had performed the two operations, and that has set me rather against it. She had had a bad tear of the cervix and of the perineum. She was afraid to take ether, and did not wish to take it more than once, and I was persuaded to perform both operations at one time. She never recovered from the ether. Vomiting continued five days, the weakness finally resulting in heart-clot and death. I have, however, repeatedly had patients under ether for two or three hours in the performance of other operations, and have never had any bad result from the prolonged use of the anæsthetic. In a case where there are good reasons making it desirable that the two operations should be done at one sitting, I should perform them. The advocates of the double operation are numerous, while those who oppose it are few in number.

We have here, as you see, a perfect result. The perineum is at least an inch and a half in depth, and is proportionately thick. In this case, I used a self-retaining catheter. The bowels were opened with castor oil on the fourth day after the operation, and again one week after the operation. The stitches were then removed. Union has taken place throughout, and in a short time the patient will leave the hospital.

MENORRHAGIA DUE TO THE PRESENCE OF FUNGOUS VEGETATIONS.

This patient is twenty-nine years of age, married, and had one child nine years ago. Since then she has had two miscarriages, which occurred four or five years ago. Three years ago she was operated on at another institution for laceration of the cervix. She complains of pain in the left ovarian region, the pain extending down the thigh. She also has metrorrhagia. When there is pain, such as this patient describes, in the ovarian region, extending down the thigh, you will find that, in the great majority of cases, it is ovarian in origin. The menses occur every two weeks, sometimes oftener.

Why did this woman have two miscarriages? When a woman has had successive miscarriages, you will find that in fifty per cent. of the cases they are due to specific infection, provided they are not criminal abortions. Where such a history obtains, you should try, in a delicate way, to find out if there has been any specific disease. I have done this in the present instance, and have failed to find any evidence of such disease. Looking at her face, you see that peculiar appearance which is present in three different conditions, hemorrhage, malarial poisoning, and cancer. The cachexia produced by these different affections resemble each other so closely that it is impossible to distinguish between them. Sometimes in the cachexia of cancer there is a leaden appearance not seen in cachexia due to other causes; but this is not invariable. Her cachexia is due to loss of blood.

Before examining this patient, we may say that she has one of three conditions: fungous vegetations of the endometrium, a fibroid tumor, or possibly a polypus. As she is not thirty years old, it is not likely that she has a fibroid tumor. This growth makes its appearance more commonly between the ages of 35 and 45 years. We may therefore set that aside for the present. She tells us that she has had menorrhagia for the past nine years. If it were a polypus it would in all probability have worked its way to the mouth of the womb and have been discovered at the time that the operation on the cervix was performed. This would lead us to say that in all probability the hemorrhage depends on fungous vegetations.

The patient has been losing blood for the past two or three days. One of the best hæmostatics under these circumstances is the curette. It affords us the quickest way of stopping the bleeding. I usually prefer the sharp curette, but I have succeeded with the dull curette. This succeeds even where there are no fungous vegetations. We shall not be able to employ the curette this morning, because she is not prepared to stay in the hospital.

This patient is thin, but you must not infer that all women who lose blood are thin. On the contrary, many women who are bleeding profusely become fat, but the fat is of a flabby character.

I shall make a digital examination. I find the cervix small. The fundus is high up. The sound gives a measurement of a little over three inches. If a polypus were present, it would have to be very small, for if it were one inch in diameter the uterus would measure at least three and one-half inches. I cannot detect the presence of a fibroid tumor. I therefore conclude that the

hemorrhage is due to the presence of fungous vegetations.

I shall direct this patient to return to have the womb curetted. This is usually not a dangerous operation. The cervix will first be dilated sufficiently to permit the introduction of the curette. This will be done with the steel dilator rather than with the sponge-tents, which are a source of danger.

The curette will then be washed in an antiseptic solution, either of the bichloride of mercury or of carbolic acid. The whole endometrium will then be carefully scraped. This will remove the numerous vegetations, which consist simply of redundant tissue, the result of over-nutrition. This woman, as we have stated, had a laceration of the cervix for six years. which, being a point of irritation, invited blood to the part, and led to this over-growth of tissue. Before operating on a lacerated cervix, you should always ascertain whether menorrhagia is one of the symptoms, and if so, you should curette the womb, either some days before or at the time of the operation. I much prefer to do it at the time of the operation. After the womb has been curetted, a disinfectant solution should be employed. If the cervix were well dilated, I should not hesitate to inject a solution of corrosive sublimate. I usually swab out the womb with a strong solution of tincture of iodine. It is dangerous to inject solutions into the cavity of the womb unless the os is well open. If there is not a free escape for the fluid, the muscular fibres around the cervix may contract, preventing the escape of the liquid, and then, if the uterus contracts, the irritating solution may be forced through the fallopian tubes into the peritoneal cavity. Therefore, remember this: Never inject anything into the non-gravid womb, unless the mouth of the uterus is so well opened that the fluid may come away as rapidly as it is injected. Even when the os is well dilated, you should not inject fluids unless their use is absolutely called for.

In cases of this kind, where there is difficulty in arresting the bleeding, it is often a good plan to introduce a piece of nitrate of silver into the cavity of the uterus. A piece half an inch long may be employed. This will cause the womb to contract, and will often stop bleeding when other measures fail. But this should be done only when milder measures fail, and as a last resort.

—The president of Harvard College gets $4,000 per annum. So does the head cook in the Parker House, Boston. But neither one of them can fill the other's place.

Communications.

STYPTICS: THE ESPECIAL USE OF, IN THE TREATMENT OF DIPHTHERIA.

BY VESTA M. W. SWARTS, M. D.,
Of Auburn, Ind.

The fact that the true rationale of the use of styptics in the treatment of diphtheria does not seem to be well understood by the profession at large, is my apology for the appearance of this paper, written upon the treatment of a disease of which the literature is already voluminous. For a similar reason I shall proceed at once to the discussion of the principles involved, adding thereto a detailed account of the plan I have found most successful in practice.

The first indication in point of time and importance, in every case of diphtheria, is to prevent the local extension of the disease; as by this means we may expect to limit constitutional infection to a degree compatible with returning health. I believe that this can be done in all uncomplicated cases of pharyngeal diphtheria by the judicious and timely use of that class of astringents known as styptics.

The mucous membrane involved is in process of exudative inflammation, with tendency to fibrinous effusion, and infested with masses of bacteria which permeate surrounding tissue, live and multiply upon and within the exudation, and unite with it in the formation of the diphtheritic membrane.

In treatment, it matters not, outside of prophylaxis, whether these vegetable organisms are the carriers of the disease or not; nor yet that they are found in small numbers in healthy secretions. The whole process is pathological, and their aggregated numbers certainly produce a mechanical disturbance sufficient in some cases to be noticed by the patient and spoken of as if a hair or needles were sticking in the throat. We certainly know that without these micrococci diphtheria does not exist, and if their growth can be early prevented, the process ends. Theoretically, this can be done by depriving them of their pabulum—the material upon which they live. Practically, styptics stop the fibrinous exudation and lead to recovery. Mild astringents only make time for other agents, or too often prolong the case until general sepsis ends it. Ice, the actual cautery, collodion would be serviceable, but owing to the difficulty of their application, our best known agent is likely the solution

of sub-sulphate of iron. It is decidedly styptic, non-irritating, and the effect of each application lasts longer than that of any other drug I have used, not excepting the valuable perchloride.

The best plan I have ever used is the following: Dilute Monsel's solution with nearly half its volume of glycerine, and apply with a camel's-hair brush over the diphtheritic membrane and adjoining tissue, requiring the patient to swallow a few mouthfuls of cold water immediately after the application to each locality, until all the affected portions are reached. Small children who refuse to drink, should have cold water thrown with a syringe far enough back to reach the pharynx or to compel them to swallow.

These applications should be made from two to four times a day, taking care that the night interval be as short as possible. In from two to four days there will be left only portions of partly adherent membrane, and the patient complains that the application is becoming painful, and that the throat feels perhaps worse. This is an indication that the mucous membrane, now stripped of its epithelium, needs protection. It should now be thoroughly dusted from three to six times a day with powdered sulphur, which has been some time exposed to the air, and therefore contains free sulphurous acid. Applied in this manner it protects the young epithelium, and renders the decaying mass aseptic. The styptic should be promptly discontinued so soon as the disease is under control; if used longer, it destroys these new cells and hinders the process of repair. The sulphur should be used for a few days longer.

Sometimes it will be well to give the patient the comfort of this protection a short time after each application of the sub-sulphate, and for very small children a weaker solution may be used. For cases seen early, the distinct localized red surface may be brushed with a mild solution, and after a few swallows of water are taken may be covered with the powder. The systemic effects of the disease ought always to be closely watched, and in bad cases it will be necessary—

1. To prevent extensive glandular infection; and for this purpose repeated applications to the neck over the region of the submaxillary and cervical glands of turpentine and oleic acid, or turpentine and lard, equal parts, have proved serviceable.

2. To allay irritation of terminal nerves in order to hinder increase of blood-supply to the affected membrane, and to prevent to some extent the increase of heat production (fever). Aconite in small repeated doses, quinine, or if the patient be restless, chloral cautiously administered, will aid materially in meeting this indication.

3, and important, it will be necessary to prevent, if possible, the prostration incident to the disease by the early and continuous use of alcoholic stimulants, until convalescence is fully reached, and the assimilation of food sufficient to meet the demands of the system.

That other and important indications for treatment will sometimes arise, and that by reason of complications some cases must end fatally, I am well aware; also that this kind of local treatment cannot be applied to the larynx, and that systemic remedies intended to limit exudation often fail entirely of their purpose; and yet I ask for styptics only their proper place in the therapeutics of this disease when I urge the timely use of such measures as tend to "starve out" those vegetable marauders, the micrococci of diphtheria, ere they block up the avenues of life or by general infection destroy it.

A CASE OF EPILEPSY APPARENTLY DUE TO GENERAL IRRITATION, AND CURED BY CIRCUMCISION.*

BY WHARTON SINKLER, M. D.,

Of Philadelphia,

More or less difference of opinion exists as to the influence of peripheral irritation in the production of epilepsy. It is generally agreed that sexual excesses or irritation of the generative apparatus can alone cause true epilepsy; but most writers admit that self-abuse or excessive venery bear a large part in the etiology of the disease, and that, if once established, these habits tend to aggravate and render it more difficult of cure.

Gowers thinks that masturbation in boys is a frequent cause of fits, which, while not genuine epileptic seizures, are convulsions of an hystero-epileptic kind.

Irritation of the prepuce or glans penis, even when not associated with masturbation, is believed by many to be the source of divers reflex nervous disorders, including epileptic convulsions, and many operations of circumcision have been done to relieve these conditions, with varying success.

To add some testimony to the subject, I wish to report to the Society the following case of marked epileptic fits associated with

*Read before the Philadelphia Neurological Society, December 27, 1886.

irritability of the genitals, and in which the attacks ceased after the operation of circumcision.

Frank P., colored, æt. 3 years and 5 months, came to my clinic at the Infirmary for Nervous Diseases, July 19, 1886. His parents are healthy, and have five other children; none of these have had fits, but one had chorea. He was well until December, 1884, when he had two spasms. These were attributed to teething and taking cold. In January, 1885, he had another fit. The attack was marked, and lasted three or four minutes. Since that time he has averaged one fit a week. The attacks are severe, the convulsive movements being general, and afterwards he is dull and sleepy. For several days past he has had an attack every day.

The child is well nourished, and shows no sign of rickets except that he is backward in teething. He is intelligent, and talks freely. The prepuce is elongated and inflamed at the edges, but can be retracted over the glans. Any touch, however, brings on an erection of the penis. The mother says that he handles the penis frequently, and seems to have some discomfort about it.

He was ordered potass. bromid., gr. ii. ter die. In one week returned and reported having had one attack. The bromide was increased to gr. v. ter die.

August 2. The boy has had thirty-five or forty attacks during the past week; some days twelve or fifteen fits. He has become unable to speak, and seems to have lost his intelligence. The genitals are very irritable; a touch of the penis makes it rigid. Circumcision was advised, and the operation was performed by Dr. H. E. Goodman on August 9. The bromide was continued in five-grain doses three times a day.

In the week after the operation was done he had two attacks. Since then there have been none. The bromide was taken for about three weeks.

I examined the child on December 27, and he seemed well. He was bright and active, and talked freely.

Gowers speaks of a case of epilepsy in a boy of thirteen years who had twelve or fourteen attacks a day under various treatment. It was found that he was addicted to self-abuse, and a blister on the prepuce reduced the fits to from two to seven a day. Circumcision was then performed, and the attacks ceased at once and did not recur. This author advises circumcision in all cases of epilepsy when masturbation is suspected.

A READY METHOD OF INDUCING RESPIRATION IN INFANTS BORN ASPHYXIATED.

BY ENOS T. BLACKWELL, M. D.,

Of Cedarville, N. J.

The birth of an asphyxiated infant makes an immediate and imperious demand upon the resources of the accoucheur that the life of the new-born may be saved. The call will be variously met as the practitioner has experience and good sense. Coolness and tact are requisites of success, presence of mind being in the highest degree indispensable.

The beginner in the art will, perhaps, hurriedly order hot water in which the infant may be immersed, that the shock of the heat upon the surface may induce respiration by reflex action through the nervous system. This procedure involves the cutting of the cord, and the neglect of the mother, who meanwhile is liable to hemorrhage, or other grave trouble. At best, it is a clumsy method; and the water, if not quite hot, produces a condition the opposite of that desired. He may dash cold water upon it, possibly, without severing the cord; but there is danger of deluging the lying-in couch, and so, perhaps, he separates it as in the aforesaid manner—losing time and neglecting the mother meanwhile.

He may even, if an unthinking person, puff his own devitalized breath into its mouth and nares—of course with an unfavorable result. Flagellation with the hand, or some suitable substitute, is resorted to by some.

A procedure brought forward a year since at the annual meeting of the Medical and Chirurgical Faculty of Maryland, under the name of the Schultze method, has obtained some currency in medical literature. It consists in swinging the fœtus by the shoulders alternately forward and backward, the axillary articulation being the pivot about which it is made to revolve. This requires the separating the infant from the mother and her abandonment during the efforts at resuscitation of her offspring. The manœuvre would seem likely to end in dislocating its shoulders by the inexpert.

A method embracing, perhaps, the same principles, which is immediately applicable without an instant's absence from the mother's side, and gives excellent results, was described by me in the MEDICAL AND SURGICAL REPORTER for 1879, vol. xvi., p. 527. This has seemed, in my experience, to establish breathing in all cases in which

death had not absolutely taken place. I make no apology for its reproduction here, as it merits a wider recognition than it has received, and a thorough trial by all who are engaged in the practice of midwifery. By an inadvertence, the principle is referred to the Marshall Hall system, but is more nearly allied to that of Sylvester.

"In the resuscitation of asphyxiated infants newly-born, I have long used a procedure embodying the principles of the Marshall Hall method, viz., by tossing the child with a quick motion, the placenta being still attached. The rapid movement causes the arms to fly up, lifting the chest-walls, and causing the infant to take in air by a sudden sob. The method may appear rude, but it has succeeded in many instances apparently desperate. It has the merit of instant applicability, with very quick results; and experience with it induces me to believe it unfailing in the recovery of newly-born infants perishing from asphyxia." In the procedure, the head, neck, and shoulders are supported in the palm of one hand, while the buttocks rest in that of the other. A few tosses are generally sufficient to elicit a cry. As a part of the literature of a subject that must interest the great body of medical practitioners, and which is strangely neglected in some systematic works on midwifery, I recall the attention of the profession to a plan which I believe has special merit.

THE SANITARY QUALITIES OF ARTIFICIAL BUTTER.

BY JACOB R. LUDLOW, M. D.,

Of Easton, Pa.

The late Prof. Hughes Bennett is quoted as saying that the great cause of the prevalence of pulmonary phthisis was the scarcity of good butter and the abundance of pastry cooks. The butter supply has always been inadequate. Years ago, farmers and laboring men used pickled pork and bacon as fat foods, and butter only as a luxury. But now-a-days, everybody eats butter, whether he live in a shanty or in a palace, and the demand is so great that if we were dependent exclusively on the cow for our butter, the price would exclude it from the tables of all except those in comfortable circumstances.

Within a few years science and art have given us a substitute in oleomargerine and butterine. The skill and success that have been shown in its manufacture are quite phenomenal. It is really a triumph in its way. It is much better and more wholesome than much of the butter found in the markets. It has brought down the price of butter fully fifty per cent. The quality is uniform and the sources of supply inexhaustible. It is really a boon to the poor man and the man in moderate circumstances; yet it is denounced and misrepresented by the dairy interest because its extended use has diminished their profits.

It is called "stuff," and "nasty," and attempts are made to excite prejudice against it as unwholesome; laws are passed taxing it, and more or less prohibiting its manufacture and sale. These laws and methods have chiefly one effect: they raise the price of butter, whether dairy or factory, on the consumer. They never will prevent its manufacture and sale. So long as men can make artificial butter which cannot be distinguished from dairy butter by sight, taste, or smell, so long will it be made and sold; and legal restrictions advance the price without diminishing the profits of its manufacture.

In the interest of the masses, I think the profession should protest against unnecessarily adding to the cost of a food so valuable and important. The rich man may enjoy his gilt-edged butter, but, without this aid, the poor man must be forced to use the inferior grades of dairy butter, strong, garlicky, carelessly made, and often unwholesome.

The wise fools calling themselves reformers, who, a few years ago, went about lecturing upon the injurious nature of fat as a food, did a great deal of harm in exciting a prejudice against fat ham, bacon, pickled pork, and other forms of wholesome fats; and now, a delicately prepared fat, so closely resembling butter as to be easily substituted for it, is to be driven if possible from the market for the sole purpose of adding to the profits of a special industry. Congress had better subsidize the dairy interest from the surplus in the treasury than to collect this additional tax directly from the people.

It is proposed to reduce the tariff on sugar. This would very likely not reduce the price of sugar to the consumer, and if it did, so much the worse. Sugar is too cheap already, and too much is eaten for the good of the public stomach, while a palatable fat food, which the people need, is discountenanced by a prohibitory price.

I have no interest, pecuniary or otherwise, in either dairy-made or artificial butter, but, as a practitioner of medicine, my attention is called to forms of food that may not make a recourse to cod-liver oil so often a necessity.

Hospital Reports.

PHILADELPHIA HOSPITAL.

Service of Dr. Theophilus Parvin.

Dr. Parvin is noted for his punctuality in commencing his lectures; hence when he entered the room and the clock marked ten minutes after the hour, he laughingly said that he was compelled to confess that he was a little late—the remorseless clock would not lie, and it warned him that he was behind time. He recalled that when he was a child, there was a good old minister in his neighborhood who had been a soldier in the war of the Revolution, and who, owing to the sparsely settled condition of the country, was obliged to travel about and preach in many separate places. As his means of transportation were not very certain, he was wont to announce that, "the Lord being willing, he would preach next Wednesday evening, at early candle lighting, as there will be a moon on that night if it does not rain." This allowed him a good margin. But now it is different; for clocks abound, remorselessly recording not only hours but minutes, and ten or fifteen minutes amounts to something; it is, however, a legal fiction that it is always one hour until the next arrives; therefore, as it is not yet ten, you must, despite the dictum of the truthful clock, conclude that it is only nine, and that I am therefore on time.

Paraplegia in its Relation to Labor.

Dr. Parvin had two very interesting cases to present. One was a case of paraplegia during pregnancy and labor. There are two forms of paraplegia in connection with pregnancy and parturition; the one where it precedes pregnancy, the other where it occurs during it, when it is often reflex. Now, the question very naturally arises as to what effect paraplegia has upon the progress of labor. If only the lower limbs are affected, then no influence whatsoever is exerted upon the labor; indeed, under these circumstances the labor may be even more rapid, because as the pain or suffering is not experienced, so the expulsive efforts are not retarded, as they usually are, when nature seems inclined, by this retardation, to wish to render a temporary respite to the woman's suffering. If, however, the abdominal muscles are involved, we can readily understand how labor will be delayed, because, of course, these muscles greatly aid the uterine contraction in its expulsive efforts. In this case there was no delay; if anything, the labor was more than usually rapid.

Rheumatism in Pregnancy.

The second case is one where pregnancy and labor were complicated with rheumatism. For some weeks before labor this woman suffered with a violent attack of acute articular rheumatism, which lasted through labor and continued for some time thereafter. This is the first case of the kind that Dr. Parvin has ever seen; during labor her temperature was 103⅖°, which, under other circumstances, would have occasioned serious alarm. Her temperature continued from 100° to 102°, and she suffered greatly. It was customary for the older obstetrical authors to dwell upon rheumatism of the uterus, which they claimed occurred not only during pregnancy but in labor as well, and it was to this rheumatism that they were frequently wont to ascribe the etiology of dysmenorrhœa. Indeed, the famous guaiac prescription of Dr. Dewees for this complaint, which was the ammoniated tincture of guaiac, had, for its *raison d'etre*, the idea that uterine rheumatism was at the basis of dysmenorrhœa. You never hear nowadays of rheumatism of the uterus; that which was once so-called, we now know to be a sub-acute inflammation of the peritoneum or of the muscular tissue of the uterus itself. Another patient in the expectant ward, was seized with most violent abdominal pain, and it was supposed at first that she was in labor, though the natural duration of pregnancy had not been reached. She was removed to the lying-in ward, but did not bring forth. Her suffering was intermittent; why, I do not know, unless it is that it is the rule for women in pregnancy to have intermittent contractions, which however are usually painless, while they are painful if there be inflammation of peritoneal or muscular uterine wall. As soon as I saw this woman knew that her pain was not that of labor, because in true labor the sufferer is *girdled*, as it were, with pain—the pain commences in the back and circles both sides round to the front. Here the pain was confined to the anterior uterine wall.

Auscultation in the Diagnosis of Pregnancy.

We now come back to the diagnosis of pregnancy, the subject that we have been investigating. I recommend mediate in preference to immediate auscultation, for several reasons. It is not very delicate to apply the ear directly to the abdomen; the position of the examiner would be more or less constrained; the circulation in the vessels of the neck would be interfered with, which might give rise to deceptive sounds; your neck

muscles would be strained, and if you wear a beard it might also cause misleading sounds. Again, unless you use a stethoscope, it will not be easy to locate the maximum of intensity of the sounds you hear. I remember being one time in the Fever Hospital of Dublin with Dr. Kennedy, and seeing him use a stethoscope, maybe eighteen inches long. To my query why he used such a long instrument, he whispered the reply that it was to keep the vermin off; so that under certain circumstances this may be an additional reason for the employment of this instrument.

The fœtal heart-sound can be usually heard at the end of three months; I would say that it is then audible in three-fourths of all cases; at 3½ months it is heard in more, and you will rarely fail to detect it at 4½ months, certainly not oftener than once in one hundred cases. The detection of the fœtal heart-sounds is an absolutely positive evidence of pregnancy, and it is the only infallible symptom we have. When we have once heard it, we know, beyond question, no matter how great may be the negative evidence, that the woman in whose abdomen it has been heard is pregnant. What has been erroneously called the placental souffle is not diagnostic. This sound has no pulsation, which negatives the old idea that it was caused by the circulation in the aorta or in the iliacs. It is heard most distinctly on the sides, and may be compared to the sound produced by softly pronouncing the word *voo*. It is synchronous with the maternal pulse, and is usually heard most distinctly on the left side. The only things with which it could be possibly confounded would be an anæmic souffle, or the bruit caused by valvular heart disease of the mother. We must remember that the blood vessels of the uterus enter that organ at the sides—when we have a column of liquid flowing through vessels of a uniform calibre no sound is produced, but if these vessels become suddenly enlarged, or if a number of new vessels (the combined area of which is greater than that of the primitive vessel) be formed, then the flow of liquid will give rise to a sound. If you go into a forest in "the leafy month of June," when the trees covered with leaves offer an obstruction to the free passage of the wind, you will hear musical sounds that are not produced in the cold, cheerless, leafless days of February. The deep and narrow river flows noiselessly on to the ocean, but should its channel suddenly widen, then there is a rippling and a gurgling of the waters. So is it with this *uterine* souffle, to which, with strange and inconsistent persistency, the term *placental* still adheres—for we now know that the placenta has nothing to do with its production. Some years ago I read in an English medical journal of good repute, a communication from some physician, who claimed that he could diagnose the sex of the fœtus in utero, according as this souffle was the more intense on one side or the other. Notwithstanding the absurdity of this statement, it passed unchallenged; and in spite of the omniscience of medical journals and medical editors, it was never denied. It is a fact that this sound may be heard one, two, or even three days after the completion of labor. Is it then diagnostic of pregnancy? Well, we can hardly believe that a woman may become pregnant three days after she has given birth to a child. It simply means that the blood is flowing from vessels of a lesser into vessels of a greater area; so, therefore, anything that causes an increased vitality of the uterus may give rise to it. It may be heard in probably fifty per cent. of the cases of soft uterine fibroids. It is usually heard first about the fourth month, whence it grows gradually more distinct until the seventh month, from which time it remains stationary to the end of pregnancy. Thus, then we see that the souffle is not diagnostic of pregnancy, and even if we accept it as a collateral evidence, it is of no value in guiding us as to the life or death, or healthy or unhealthy condition, of the fœtus. On the other hand, the fœtal heart-sounds are not only diagnostic, but they inform us also as to the condition of the child. Obstetric auscultation requires a long and thorough apprenticeship. I remember Professor Samuel Jackson asking me one day if I had been to the clinic, and when I replied in the negative, he told me that I ought never to miss an opportunity of seeing a sick person. So I say to you, you should never miss the opportunity of ausculting a pregnant abdomen. The fœtal heart commences to pulsate a few days after conception, but, as I have already said, it is not available for diagnostic purposes until about the end of the fourth month. Where shall you listen for it? Remember that the shape of the uterus varies with the progress of labor. At first it is spheroidal, and the fœtus may lie anywhere. By the seventh month it is ovoidal, and then the fœtus has assumed the most comfortable position, which it thereafter maintains. In 96 out of every 100 cases, this position will be with the head downwards. Early writers used to teach

that up to the seventh month the fœtus sat on the brim of the pelvis, and at this time the head growing too heavy for this position, it toppled over and became a vertex position; and with a marked lack of gallantry they were accustomed to say that this occurred earlier in boys than in girls, because the heads of the former developed more than the latter. Of course, we now know that this position is assumed because the uterus is best adapted for it. If we are listening for the heart-sounds as early as the third or third and a half month, then we should place the stethoscope in the axis of the superior strait and auscult perpendicularly to the fundus of the uterus. In 1832 an instrument was devised called a metroscope, which was designed to be introduced into the vagina for ausculting purposes; it did not meet with much favor. An effort is now being made to revive it, but without much success. It might cause abortion, and is not to be recommended. If we draw a line from the umbilicus to the superior spinous process of the ileum, we will hear the heart-sounds about its middle, and usually on the left side. We can, as I have said, form an opinion as to the condition of the fœtus. The sounds will vary from 120 to 160 per minute, averaging 140. If they are only 90, or are up to 200, we will know that the child is in danger. The sounds may be likened to *tic tac, tic tac*, the interval between the tac and the tic being twice as long as that between the tic and the tac. If these sounds are not distinct, if they are wavy or weak, then we know that something is wrong. When you are to auscult a pregnant woman the room should be quiet, and her bowels and bladder should be empty. It will be best to have the abdomen uncovered, though the interposition of a piece of thin muslin will make no material difference. A woman may simulate the fœtal movements; she may testify to the subjective, and in certain pathological conditions, we may have many of the objective signs of pregnancy; but no power can produce the fœtal heart-sounds save the presence of a living fœtus; and when we remember that the reputation and happiness, aye, the very salvation of a woman may rest on our opinion, we should not fail to realize the great responsibility that rests upon us.

—According to the *Lancet*, precipitated chalk forms the best basis for a tooth powder, to the base of which may be added pulv. saponis and ol. eucalypt., a drachm of each; and, if there is no objection to the taste, half a drachm of carbolic acid.

Medical Societies.

THE BALTIMORE ACADEMY OF MEDICINE.

Stated meeting, January 18, 1887.

Owing to the absence of both the President and Vice-President, Dr. T. A. Ashby was elected President *pro tem.*

Alcohol as an Anæsthetic.

Dr. W. Chew Van Bibber related three cases in which complete anæsthesia was brought about during labor by large doses of alcohol. The uterine contractions were regular and easy; there was no trouble with the placenta, nor was there any post-partum hemorrhage. The patient was so completely under its influence as to experience no pain, and was entirely unaware of the passage of the child from the uterus. He thinks its action compares in these cases very favorably with that of chloroform.

Dr. T. A. Ashby has seen one major operation performed while the patient was under the influence of alcohol. The operation took an hour and a half. In this case, however, the whisky (that was the form employed) was hardly pushed far enough, as the patient was somewhat hilarious during the operation. In this instance, however, he thinks the efficiency of the agent was greatly increased by fortitude and love for the whisky on the part of the patient.

Dr. W. Chew Van Bibber has employed alcohol in puerperal eclampsia for years with the happiest results. He keeps the patient perfectly relaxed for twenty-four hours. He has never had any reason to doubt its efficiency in these cases.

A New Instrument.

Dr. W. Chew Van Bibber also showed an instrument devised by him for use in circumcision. It is in the form of a punch, and is so arranged as to cut from the foreskin a triangular bit of the tissue.

Dr. A. B. Arnold corroborated the statement by Dr. Van Bibber that the skin after circumcision retracts to an astonishing degree.

Diphtheria Treated by the Out-door Method.

Dr. W. Chew Van Bibber then referred to a case of diphtheria that he had recently treated successfully as an out-patient. The patient was a girl who presented herself with both tonsils covered with diphtheritic ulcers and patches. The pharynx was likewise involved. Cervical glands swollen and tender.

A very bad odor came from the throat. He looked upon it as a grave case. His treatment was as follows. He gave her four prescriptions:

No. 1. Brandy, carbolic acid, and quinia.

No. 2. Quinia grs. iv, whisky ℥j; ℥ss every two hours.

No. 3. Was a disinfectant to be used as a gargle.

No. 4. Was composed of powders of sulphur grs. x each, to be placed dry in the mouth.

Under the circumstances he thinks it remarkable that the girl should have recovered.

Dr. W. Chew Van Bibber then read a paper upon

The Diagnosis of Cancer of the Mesentery.

(*See page* 193.)

DISCUSSION.

Dr. A. B. Arnold considers diagnosis in these cases very difficult. He can only say that he has on several occasions suspected the condition, but has never had his suspicions verified by an autopsy.

Dr. John Uhler thinks we might be aided in our diagnosis in these cases by the fact of the mobility of most of the abdominal contents. By causing the patient to alter his posture he thinks the tumor could be made to change its position.

Dr. A. B. Arnold read a paper on

Neurasthenia.

DISCUSSION.

Dr. F. T. Miles was glad to have heard this paper. He has seen a number of these cases, and thinks the picture drawn by Dr. Arnold in his paper represents them perfectly.

He thinks the larger number of these cases, instead of being accompanied by dyspepsia, really result from dyspepsia. Thinks the cerebral symptoms result from disorders in the digestive tract. Thinks the number of symptoms given by neurasthenics indicates a very general derangement of the nervous system.

It is his experience that persons with real spinal disease tell their symptoms in a very few words, but where the disease is imaginary, as in neurasthenics, the train of symptoms is almost endless. He agrees with Dr. Arnold that neurasthenia is liable to blend and glide into melancholia and grave cerebral disorders.

He referred to the permanence of many of the peculiar phobias exhibited by neurasthenics. A gentleman while in a neurasthenic condition suffered from the fear that his wife was becoming bald; he recovered and was in the habit of ridiculing this diseased notion. One evening while at a company his wife's false hair became accidentally disarranged, when the old fear immediately returned to the gentleman. In the case just referred to, improvement in personal hygiene resulted in recovery.

Dr. A. B. Arnold is gratified at hearing Dr. Miles agree with him. Hitherto neurasthenia has been obliged to fight its way into general recognition. In most of the later works devoted to diseases of the nervous system he finds it occupying a prominent place. He don't think Dr. Beard has received the proper recognition in his own country.

Dr. H. P. C. Wilson thinks many of the maladies seen in young girls are attributable to a defective system of education, in which physical training is almost completely subordinated to mental exercises. There is no doubt that such a condition can only result in exhaustion of the nervous forces.

Dr. A. B. Arnold related a case in his own practice in which he was called to see a young lady. He could not determine her ailment, nor could he relieve her by any means known. Becoming discouraged, he ceased his visits. Shortly afterward he saw her on the street, a picture of health. Enquiry revealed the fact that she had had a lover who had left the city; this was the cause of the condition in which he first saw her. He had now returned, and this he supposed to be the reason for her return to health and spirits. He is puzzled to know what treatment a physician should adopt in such a case.

Dr. T. Barton Brune read a paper upon

A Reducing Substance in the Urine Resembling Glucose.

Dr. John Uhler read an article from the *Boston Medical and Surgical Journal*, by Dr. Harrington, upon

Potassium Bichromate as a Source of Poisoning.

Following upon this he read a letter from a chemist in charge of the large chrome works in the North; in which this gentleman endeavors to show that the article in the Boston paper is not a statement of facts, and that its author, upon chemical grounds, is not justified in making the statements. He says: Dyers who use the salts of chrome acid are not affected. Weavers who employ the stuffs that have been dyed with those colors are not poisoned.

In the United States there is nothing known as chrome disease of the skin. Ex-

cepting the loss of the nasal septum, the workers in these establishments are as healthy as outsiders. Those who spend a short time only each day in chrome works are in no way affected in health.

Dr. John N. McKenzie said in his observations upon the perforation of the septum, as a result of the action of chromium, it is seen that perforation may occur in some cases so early as twenty-four hours after first working in the substance.

Chrome acid is limited in its action, being converted, when acting, into an insoluble oxide. He has found ulceration on the mucous membrane of the nose, but not of the pharynx. He called attention to the fact that when the substance gains entrance to the system it always finds its way to the respiratory tract.

Perforation of the septum from chromic acid may be differentiated from that resulting from syphilis, by the fact that in the former there is no change in the out shape of the nose, while in the latter the outline of the organ is altered.

NEW YORK ACADEMY OF MEDICINE.

Stated meeting, January 20, 1887.

A. Jacobi, M. D., President, in the chair.

Reports of meetings of the sections were read. Dr. E. Darwin Hudson had been elected chairman of the section in theory and practice, and Dr. R. C. M. Page secretary; Dr. R. F. Weir had been elected chairman of the section in surgery, and Dr. Robert Abbe secretary; Dr. E. L. Partridge had been elected chairman of the section on obstetrics and diseases of children, and Dr. I. E. Holt secretary.

The Value of Quinine as an Antipyretic in Pneumonia.

Dr. John H. Ripley read the scientific paper of the evening, in which he gave a summary of the treatment of forty-eight cases of pneumomia in St. Francis Hospital by quinine, administered for the purpose of reducing the temperature, it being given in no instance in which the temperature had not been above 103° F. There were only about six of the cases in which the temperature fell after its administration more than two degrees; in half the cases it fell only one and a fraction of a degree, and in the other half less than a degree. Its fall was not regular; the duration of the fall was uncertain, it was generally short. In as much as there were recessions of temperature in pneumonia even when no drugs were administered, it could not be said that in all these cases the fall was due to the quinine. Moreover, the quinine produced in many cases unpleasant effects. In large doses it would cause vomiting and disturbance of digestion for some time afterward; and even in moderate doses it would give rise to anorexia and nausea. It also made the heart's action weak. Among the effects on the nervous system were noticed somnolence, delirium, in two cases opisthotonos, etc.

Dr. Ripley concluded that quinine was a feeble antipyretic in pneumonia, but that its use was not justified; that if an antipyretic effect was desired there were more efficient drugs than quinine. He said further, that in his opinion the administration of drugs for the reduction of temperature in fevers was being carried beyond proper limits; that the importance of reducing the temperature, especially when only moderate, had been exaggerated.

The views regarding the use of quinine as an antipyretic in pneumonia expressed by Dr. Ripley, were coincided with essentially by Drs. Putnam Jacobi, J. Lewis Smith, Fruitnight, Castle, Billington, and Holt. The president had some years ago given quinine to children in pneumonia when the temperature was sufficiently high to call for an antipyretic effect, and with good results; but he administered it usually in the morning, or when the fever was not highest, so that it could be taken up; if hypodermically, he gave the carbamide of quinine. He gave doses then regarded as large, but now not so considered—six to ten grains a day to children. The very large doses now given were regarded by him as injurious. He seldom gave quinine as an antipyretic in pneumonia now, because antipyrine, for instance, was more efficient.

Adjourned.

—Winkelmeier is the name of a giant who is now on exhibition in London. He is eight feet and nine inches in height, and is therefore more than a foot taller than Chang, the Chinese giant. He was born at Freidburg, Upper Austria, in 1865, his parents being people of humble life and normal size.

—"Did you carry that prescription to old Mrs. Smith last night?" said the doctor to his office boy.

"Yes sir."

"Did she take it?"

"Yes sir."

"How do you know?"

"Crape on the door this morning."

Management of Simple Constipation.

Sir Andrew Clark thus writes in the *Lancet*, January 1:

The untoward consequences of constipation are always considerable and sometimes serious; but greater than they—greater than the anæmia, the blood-poisoning, the headache, the nervousness, and the heart disorder which arise out of fæcal retention—are the untoward consequences of ignorant and unskillful domestic management.

For two days a patient has had no relief to the bowels. He has been traveling, or he has changed his diet, or his accustomed routine has been in some other way interrupted. The subject is seriously considered: in the light of an excited self-consciousness impending dangers are seen, and forthwith he determines to take "a dose." But the taking of doses is an inconvenient and a disagreeable procedure, and so it is settled that the dose shall be a good one—such a one as will speedily and effectually overcome the constipation and relieve the patient of his trouble. The dose is taken, the bowels (small, perhaps, as well as large) are emptied of their contents, the object of treatment has been achieved, and all for a time seems well. But the next day arrives, and there is no fresh movement of the bowels; even a second day passes, and they are still inactive. The patient is more uncomfortable than he was before he took his "dose." What is to be done? Matters cannot continue as they are. Plainly the medicine first emyloyed has confined the bowels, and so another must be taken which shall be free from this disadvantage. The other is taken; again the bowels are freely moved, and a liquid, light-colored, mucoid, and feculent discharge attests the success of the new endeavor. But the bowels fail to resume their periodical discharges; the patient becomes worse than ever; again he flies to artificial help for relief; again he is disappointed in recalling nature to her own ways; and at last the bowels, robbed of their normal conditions of action and exhausted by frequent irritation, refuse to act at all except under the spur of strong aperients frequently repeated. With few exceptions, no person has passed through this experience and fallen under the tyranny of aperients without finding his life invaded by a pack of petty miseries which lower his health, vex his temper, and cripple his work. Now, for the most part all these troublesome consequences of constipation may be avoided by attending to the conditions of healthy defecation. The chief of them requiring consideration at this time, and assuming the integrity of the nervo-muscular apparatus of the bowels, are plenty of solid and liquid digestible food, a fair amount of refuse matters in the colon, regard to the promptings of nature, daily solicitation at an appointed time, the co-operation of expectation and will, and contentment with a moderate discharge. I propose to discuss briefly each of these conditions.

1. Plenty of solid and fluid digestible food. People leading a sedentary or a society life become disposed to eat too fine foods, and to drink too little liquid. Among the results of such habits are a general want of nervo-muscular vigor, a deficiency of intestinal secretion, and an insufficient amount of refuse matter in the bowels to secure daily relief. To correct this without the help of drugs, coarse and irritating foods are taken. For a day or two perhaps they succeed; but after a time they provoke catarrhal irritation, and either increase the constipation or bring about lienteric diarrhœa. As a rule, it is a practical error to treat constipation by means of hard, indigestible, and irritating articles of food.

2. A moderately full colon is essential to the sufficient periodical discharge from the bowels. It is true that the ordinary peristaltic action of the bowels is automatic, and substantially independent of external stimulation; but it is, I think, equally true that for the stronger peristaltic action which, accompanied by inhibition of the associated lumbar centre and relaxation of the anal sphincter, issues in normal defecation, an external stimulus, the stimulus of an adequate amount of retained fæces, is necessary. If by an aperient, or by any other means, the colon is more or less completely emptied of its contents, defecation will be suspended until the colon becomes again more or less full; it cannot act independently of the appointed conditions of action; it cannot make bricks without straw.

3. Regard to the promptings of nature. When the lower part of the sigmoid flexure is full, sensory impulses are sent to the nervous centres, and these are responded to by

discharges which not only excite vigorous peristalsis in the upper part of the colon and solicit the coöperation of the will, but tend to inhibit the lumbar centre and to bring about relaxation of the anal sphincter. The conditions of defecation are present, and it needs only a patient effort of will and concurrent expectation to originate and complete the operation. But when attention to these promptings of nature is denied they cease for the time; and although they recur and suffice for action, the denial, if often repeated, blunts the sensibilities of the parts concerned, deprives us of the normal intimations of the need for relief, and brings about a form of constipation difficult to cure.

4. Daily solicitation of nature at an appointed time. It has been found that for the great majority of people the most favorable, and also the most convenient, time for procuring relief to the bowels is after breakfast; and it is one of the greatest helps to sufficiency and regularity of action that the daily solicitation of nature should be practiced at that time. In order that both solicitation and action should become developed into a habit, it is necessary that nature should not be listened to at any other than the appointed time. And in this precept there is no contradiction of the statement made in the previous paragraph; for it is not the temporary and exceptional denial of nature with the view of establishing a regular habit of defecation—it is the repeated denial of nature with no such object in view, which blunts the reflex sensibilities of the parts concerned and brings about an obstinate constipation.

5. The coöperation of expectation and will. Many persons seek relief to the bowels without taking any pains to secure success. With some persons, indeed, such pains are unnecessary. A certain automatism has been established; and it needs only time, place, and position to set it in successful motion. But in persons whose defecation is difficult, direct attention, expectation, and effort are essential, and when patiently practiced seldom fail. The practice of slight alternate contraction and relaxation of the anal sphincter sometimes provokes exceptionally active peristalsis of the lower colon; and so, with concurrent effort, secures relief which could not otherwise be obtained.

6. Contentment with a moderate discharge. Ignorance of the average amount of fæces required for the daily healthy relief of the bowels is one of the main causes of constipation, the unnecessary use of aperients, and the evils that arise from both. For a man of average weight, consuming an average amount of food, the average amount of fæces ready for discharge in twenty-four hours is about five ounces. This should be formed, sufficiently aerated to float, and coherent. According as the cylinder is moist or dry it will measure from four to six inches in length. Now, many people expect to have a much more abundant discharge, and are dissatisfied or anxious if they do not get it. They complain of their insufficient relief, and take aperients to make it larger. For a day or two larger discharges are procured, but then, when the reserves of fæces are removed and the colon is empty, and the conditions of defecation no longer exist, more or less complete inaction of the bowels ensues, constipation (as it here erroneously called) becomes confirmed, new and stronger aperients are had recourse to, and at last the patient falls into a pitiable condition of physical suffering and moral wretchedness. And from this condition there is no escape except through the complete suspension of aperients, the renewal of obedience to physiological laws, and a courageous patience in waiting upon nature.

I will conclude these imperfect remarks by putting down as briefly as possible the instructions which I ask my pupils to give to their patients for the management of simple constipation:

1. On first waking in the morning, and also on going to bed at night, sip slowly from a quarter to a half pint of water, cold or hot.

2. On rising, take a cold or tepid sponge bath, followed by a brisk general toweling.

3. Clothe warmly and loosely; see that there is no constriction about the waist.

4. Take three simple but liberal meals daily; and, if desired, and it does not disagree, take also a slice of bread and butter and a cup of tea in the afternoon. When tea is used it should not be hot or strong, or infused over five minutes. Avoid pickles, spices, curries, salted or otherwise preserved provisions, pies, pastry, cheese, jams, dried fruits, nuts, all coarse, hard, and indigestible foods taken with a view of moving the bowels, strong tea, and much hot liquid of any kind, with meals.

5. Walk at least half an hour twice daily.

6. Avoid sitting and working long in such a position as will compress or constrict the bowels.

7. Solicit the action of the bowels every day after breakfast, and be patient in solicit-

ing. If you fail in procuring relief one day, wait until the following day, when you will renew the solicitation at the appointed time. And if you fail the second day, you may, continuing the daily solicitation, wait until the fourth day, when assistance should be taken. The simplest and best will be a small enema of equal parts of olive oil and water. The action of this injection will be greatly helped by taking it with the hips raised, and by previously anointing the anus and the lower part of the rectum with vaseline or with oil.

8. If by the use of all these means you fail in establishing the habit of daily or of alternate daily action of the bowels, it may be necessary to take artificial help. And your object in doing this is not to produce a very copious dejection, or to provoke several smaller actions; your object is to coax or persuade the bowels to act after the manner of nature by the production of a moderate more or less solid formed discharge. Before having recourse to drugs, you may try, on waking in the morning, massage of the abdomen, practiced from right to left along the course of the colon; and you may take at the two greater meals of the day a dessert-spoonful or more of the best Lucca oil. It is rather a pleasant addition to potatoes or to green vegetables.

9. If the use of drugs is unavoidable, try the aloin pill. Take one half an hour before the last meal of the day, or just so much of one as will suffice to move the bowels in a natural way the next day after breakfast. If it should produce a very copious motion, or several small motions, the pill is not acting aright: only a fourth, or even less, should be taken for a dose. When the right dose has been found it may be taken daily, or on alternate days, until the habit of daily defecation is established. Then the dose of the pill should be slowly diminished, and eventually artificial help should be withdrawn.

The aloin pill is thus composed:

℞.	Aloinæ,	½ gr.
	Extr. nucis vom.,	½ gr.
	Ferri sulph.,	½ gr.
	Pulv. myrrhæ,	½ gr.
	Saponis,	½ gr.
	Fiat pil. i.	

If the fæces are dry and hard, and *if there is no special weakness of the heart*, half a grain of ipecacuanha may be added to each pill. Should the action of the pill be preceded by griping and the character of the action be unequal, half a grain of fresh extract of belladonna will probably remove these disadvantages. If the aloin pill gripes, provokes the discharge of much mucus, or otherwise disagrees, substitute the fluid extract of cascara sagrada, and take from five to twenty drops in an ounce of water either on retiring to bed or before dinner. And when neither aloin nor cascara agrees, you may succeed by taking before the mid-day meal two or three grains each of dried carbonate of soda and powdered rhubarb.

The exact agent employed for the relief of constipation is of much less importance than its mode of operation. If, whatever the agent may be, it succeeds in producing after the manner of nature one moderate formed stool, it may be, if necessary, continued indefinitely without fear of injurious effects. But, treated upon physiological considerations, I have the belief that in the great majority of cases simple constipation may be successfully overcome without recourse to aperients.

Treatment of Scarlatina Maligna.

Before an English Medical Society Dr. Michie read a paper on the use of the vapor of an impure preparation of carbolic acid in the treatment of scarlet fever during a severe outbreak which occurred some time previously in the fishing village of Cove. He held that his treatment at once reduced the malignancy of the disease, and soon removed the poison from the place. The village of Cove has a population of over five hundred people, and, at the time of the outbreak, was in a very unsanitary condition. The number of cases was thirty in all, mostly children of school age. The outbreak commenced in a very grave and fatal form, and, in the absence of eruption, could only be designated as diphtheria of the worst type. The first three cases died on the second day without any eruption, the next two on the fourth day, when a dark, hazy eruption was making its appearance. In all, however, great swelling of the throat and extensive membranous exudation were early symptoms. Three other cases of the same kind having occurred, and isolation being impracticable, Dr. Michie was led to abandon curative for prophylactic treatment. There was immediate relief. The membranous exudation began to exfoliate; and in twenty-four hours the process was complete, and the dusky skin gave place to an extremely abundant scarlet eruption. All three recovered. A few less severe cases occurred in houses where the disease had already existed in the

malignant type, and where the vapor treatment had already been instituted. These were followed by several cases of a progressively milder type, and finally the outbreak was quelled, after having invaded nine houses and affected thirty children, of whom five died. From the above description, there could not be the least doubt of the value of the treatment. As an illustration, Dr. Michie cited that of a house of two apartments, three beds, and ten inhabitants, in which two of the fatal cases occurred. These two children were treated in a room where four other children slept, where the food for the household was cooked, and where the family congregated during the illness of the two children. The vapor-treatment was commenced in this house only an hour or two before the death of the second child, and was energetically continued for some days, when four of the family suffered, not from scarlet fever, but from a "catarrhal pharyngitis," or "scarlatina sine eruptione." No one else in the household suffered. Another case was that of a boy aged 8, who suffered from the anginous variety, with rash on second day, and who occupied one of three beds in a room measuring 13 by 14 feet, in which seven other persons, including three adults, slept. Here the vapor-treatment was early adopted; the boy made a good recovery, and no other member of the household suffered even from sore throat. Dr. Michie was of opinion that the quality of the carbolic acid had a good deal to do with the success of the treatment. It had a heavy, black, tarry appearance, as if so much coal-tar oil had been carried over in the process of distillation. Half an ounce of this was vaporized every three or four hours by placing it on a flat piece of heated iron. In this way a vapor of great density and volume was produced, which penetrated into the utmost recesses of the sick-chamber, and into the clothes and respiratory tracts of the occupants. Dr. Michie thought the success depended (1) on getting the full antiseptic value of the acid in a state of vapor; (2) on the quality used, partly tar, partly acid; (3) on the frequency with which it was applied; and (4) on the continuance of the treatment for days after the last case in a house had recovered. The more malignant the type, the more value was to be derived from the early application of the tar and acid in a state of vapor; and, whatever the type, the sooner the disinfectant treatment was brought into use, the sooner they would be able to eradicate an outbreak of so infectious a disease.

Case of Intestinal Obstruction in an Infant Caused by the Ingestion of Wool.

Dr. Wm. R. White thus writes in the *Medical News:*

I was called at 1 a. m., February 12, 1884, to see E. H., a girl twelve months old, whom I had never seen previously. Her mother gave the following history: The baby had been vigorous and healthy in every respect from birth, and had developed rapidly, being able to walk unaided and to talk considerably. Her only nourishment had been breast-milk, except now and then a little bread or cracker. She had never had any intestinal trouble until now. There had been no evacuation of the bowels for the last two and a half days, and for the last twenty-four hours the child had been very restless and uncomfortable, not sleeping, refusing to nurse, and evincing abdominal pain. To relieve her, the mother had given no medicine whatever, but had tried several enemas of molasses and water, but with no avail. The last one, administered the evening previous, had caused a severe convulsion, which, however, was not of long duration. The urine had been voided naturally, and there had been no vomiting, but frequent retching and eructation. I first saw the child about five hours after the occurrence of the convulsion already referred to, and found her lying awake, but quiet, on the bed. She was not feverish, and evidently not in severe pain. The abdomen was slightly protuberant, but neither tympanitic, unduly tense, nodular, nor tender on palpation. There was no evidence of thoracic or cerebral trouble. When asked particularly if the child had swallowed any foreign substance or any unusual or indigestible matter of any kind, the mother gave a *confident reply in the negative.*

I offered no special diagnosis, but from the appearance of the patient and the history of the case, ventured the opinion that a prompt and thorough evacuation of the bowels would effect a cure. So far as could be ascertained, the enemas had been properly administered, and had not only failed to give relief, but had undoubtedly been the exciting cause of the convulsion, hence it was thought best to discontinue that line of treatment.

I at once gave the child a powder containing two grains each of calomel and sugar, directing that the same dose be repeated in a few hours if necessary. The effect of the single dose was, however, wholly satisfactory, as I was told, on visiting the case the next afternoon, that the little patient had seemed

no worse during the remainder of the night, and that between 8:30 and 10 o'clock a. m., there were four copious and painless dejections, composed partly of normal fæcal matter, with which was mixed up a large proportion of *masses of wool fibres*, of which the quantity was so great as utterly to astound the mother. She at first did not recognize the nature of the foreign substance, but on detecting unmistakable pink and blue fibres among the rest, the case became clear to her mind at once, as she then remembered having often seen the baby picking at the fleece of the soft woollen blanket on its bed, and that she had more than once removed wads of these fibres from the child's mouth, but had no idea that any had been swallowed.

The dejections had been already disposed of in the water-closet, so the writer could only judge of the amount of wool they contained by the estimate of the mother, who affirmed it to be at least as much as she could hold in her two hands.

The baby was then running about the house, bright and well as usual, and there were no signs of intestinal trouble subsequently.

Thallin in Typhoid Fever.

The introduction of such drugs as "kairin," "antipyrin," and "antifebrin" has somewhat diverted attention from a very powerful antipyretic agent, viz., thallin. Professor Ehrlich lately presented to the Clinical Society of Berlin the results of some researches he has been making with his last-named agent, especially in the treatment of typhoid fever. (*Münch. Med. Woch.*, No. 47.) From experiment, he had found that after administering the drug to animals it was not retained in the nerve centres, but mostly in the fatty tissue of the body. He also found that there was a marked difference in toxic action, according to whether it was administered by the mouth or subcutaneously, the greater inertness of its effect in the former case being attributable to the hindrance to absorption from the presence of intestinal contents. The lesions induced by a toxic dose comprised fatty degeneration of the kidneys, necrosis of the salivary glands and pancreas, and hæmorrhagic infarcts in the renal pyramids. The chief action of thallin is antipyretic, but it is capable also of moderating inflammation. As regards typhoid fever, it was administered by Ehrlich in two different ways. The first plan consisted in commencing with doses of 0.06 gramme every hour, and reducing the dose to the minimum required to give any effect. The other plan was to commence with a minimum dose, and increase it until an effect was produced, and then to continue the prescription at the dose thus attained. The action of thallin is especially noticeable in its effect on the sensorium and general condition of the patient, who presents the appearance of convalescence, whilst the splenic swelling and roseola are still present; and if the drug be discontinued, the temperature will rise again. It is not therefore surprising to learn that, whereas of twenty-eight cases treated by bathing the average stay in hospital was thirty-seven days, of seven cases treated by thallin (minimum doses) the duration of treatment was forty-seven days, and cases on a scale of progressive doses thirty-eight days. However, Professor Ehrlich claims advantages for the drug in the absolute control it exerts over the pyrexia, and the sense of well-being enjoyed by the patient. There were no intestinal hemorrhages in these cases, and no instance of perforation. The kidneys were not affected, but sequelæ in the form of hyperæmia and œdematous swellings seemed due to the use of the drug. It was not thought that thallin had any specific action against the typhoid bacillus, but it did seem to limit the degree of intestinal ulceration. Professor Ehrlich considers it to be on a level with the bath treatment. Dr. Fränkel pointed out that if the statement were correct that thallin is not found in the nerve-centres, its action in reducing temperature was rather inexplicable. He had exhibited it in increasing doses, but could not say that the patients experienced any special benefit attributable to the diminished fever. Dr. Guttmann had not been favorably impressed by its use, and had noted the production of rigors.

Extirpation of Goitre in Berlin.

Herr Weidemann has collected and published the statistics of the operation as performed in the Augusta Hospital, Berlin, between the years 1880 and 1885. Extirpation was performed 25 times during this period, 22 of the patients being females and 3 males. Seven of the patients were in the second decennium, six in the third, four in the fourth, two in the fifth, five in the sixth, and one in the seventh. With the exception of three cases all were from one region, viz., the Mark provinces (of which Berlin forms the centre), Uckermark and Neumark being the most numerously represented. In later years an increase in the number of cases had been

noticed, and especially in Berlin. In two cases the goitre was cancerous in its nature. In three cases a history of heredity was observed. One case showed all the symptoms of Basedow's (Graves') disease. In this case the symptoms disappeared after operation. The author sees in this an indication of the correctness of the view that there is no such entity as Basedow's disease, that the first step is goitre, the other symptoms being produced by pressure of the tumor on the sympathetic. During pregnancy the tumor not only underwent a temporary enlargement, but one that to some extent was permanent. In one case that had existed from youth, a rapid develpment took place after the "change." In almost all the females affected, the menses appeared late. Three women had aborted, and at periods when the tumor caused inconvenience, but whether in consequence of the respiratory troubles could not be determined. The author was, however, disposed to look upon goitre as a factor in the late appearance of the menses, and also in the production of the abortion. At the time of operation, asphyxia had occurred in three cases, which necessitated tracheotomy in every case. The cause of the sudden asphyxia lay in atrophy of the tracheal cartilage, and consequent flattening of the trachea from pressure. In seventeen cases partial resection of the "gland" was performed, and in every case the patients are now perfectly well. Of six total extirpations, two died of secondary hemorrhage, one patient had to wear a tracheal tube in consequence of previously existing paralysis of the recurrent nerve. In the case of a boy, fourteen years of age, a pronounced cachexia has since developed, with myxœdema. Both the cases of malignant disease died, one from recurrence of the disease a few months after the operation, the other shortly afterwards from "mediastinitis."

Phosphatic Diabetes.

Dr. Ralfe recently introduced to the notice of the Medical Society of London a patient suffering from phosphatic diabetes, and read particulars of twelve others. These he arranged in groups according to the classification of Professor Teissier, who first gave a systematic account of the affection.

Group 1. Excessive elimination of phosphoric acid, associated with nervous derangement; three cases.

Group 2. Excessive elimination of phosphoric acid, associated with phthisis; three cases.

Group 3. Excessive elimination of phosphoric acid alternating with saccharine diabetes; three cases.

Group 4. Excessive elimination of phosphoric acid running a distinct course, like saccharine diabetes, only without the sugar; five cases.

All the cases, with the exception of two, were young adult males. The symptoms common to all were great emaciation, aching rheumatic pains in loins and pelvic regions, dry, harsh skin, with tendency to boils, and ravenous appetite; in some cases cataract develops. In the majority there was polyuria; in others the urine was normal in quantity, with a high specific gravity. The urea was increased in some cases slightly, in others to a greater extent; but the great feature of all the cases was the very considerable and constant elimination of phosphoric acid, with or without increase of the other constituents of the urine—a feature which distinguishes it from insipid diabetes on the one hand and azoturia on the other, with both of which it has been improperly confounded. The pathology, Dr. Ralfe thinks, depends not so much on increased metabolism of nervous matter as on defective nutrition, so that the tissues are not able to utilize the phosphorus brought to them, and consequently a greater amount passes through the system daily. In those cases in which an excassive excretion of phosphoric acid replaces saccharine diabetes, it is propable that acids like oxy-butyric-glycolic, etc., formed by imperfect oxidation of the sugar, dissolve out the earthy phosphates from the tissues, which appear in excess in the urine. As regards the prognosis in these cases, it is most unfavorable in the first two groups; country air, massage, cod-liver oil, may for a time do good, but the patients rapidly fall back, and either are carried off by some acute attack proving fatal in their exhausted condition, or drift on into phthisis, or into diabetes mellitus. The prognosis of the last two groups is much more favorable; of the three cases recorded in group three, two got completely well; the third still suffers from saccharine diabetes, but it remains in a mild form.

The Treatment of Stricture of the Urethra by Gelosine Bougies.

The *Boston M. and S. Jour.* says:

The treatment of urethral stricture by bougies of gelosine is an application of the principle whereby dilatation of the natural passages (like the cervix uteri) is effected by substances which, like laminaria, swell under moisture.

Bedoin has lately reported to the Paris Société Therapeutique satisfactory results in the use of gelosine in urethral stricture. Gelosine is the Japan sea-weed, which, in its dried state, undergoes a gradual and extreme degree of augmentation of volume when brought into contact with liquids, such as water, or the secretions of the human body.

Bedoin has devised cylindrical bougies of various sizes out of this alga, which, according to his experience (he has now tried them in several bad cases) when employed in stricture of the urethral canal effect very thorough dilatation, and with very little pain. He regards gelosine as fulfilling all the conditions requisite for the preparation of bougies which are strong and flexible, may be used with entire safety, and are sure to do their work thoroughly and effectually.

Such, at least, is the inventor's opinion. The introduction of tents into the strictured portion of the urethra was tried and abandoned about the middle of the last century, becuse of the serious accidents to which the method gave rise.

At the séance of the 7th of June, 1854, of the Paris Surgical Society, bougies of prepared sponge, as proposed by Professor Alquié, of Montpellier, were exhibited, but their use was evidently of short duration. Flexible ivory had been previously experimented with; bougies of this material possess, like sponge, the property of dilating in the canal, but, in practice, they dilated above and below the stricture faster than at the strictured portion, so that withdrawal was extremely difficult. Laminaria bougies were highly praised by Dr. Robert Newman in the *Medical Record* of July 1, 1872.

The prolonged retention in the urethra of a bougie which fills the canal, keeping up only a passive, and not a constantly-increasing distention, is very likely to give rise to serious disturbances. Even the retention of a small instrument is an evil only to be suffered on special occasions. The constantly-increasing pressure of any slowly-dilating material within the urethra is sure to prove an evil sooner or later, no matter how promising the first experiments with some new material may seem.

The Influence of Tea-poisoning on the Course of Syphilis.

In the *Ejenedelinaia Kinitcheskaia Gazeta*, No. 6, 1886, Dr. S. A. Smirnoff, the president of the Piatigorsk Balneological Society, publishes an interesting note on the subject. According to his extensive experience, Siberia sends to the Caucasian mineral waters the most obstinate and dilatory forms of syphilis. That fact may be explained to a certain extent by climatic conditions, want of timely regular treatment, and possibly also by some obscure peculiarity of the infection usually contracted by Siberian patients in China and Japan. An unmistakable influence is produced also by chronic tea-poisoning. The author speaks of so-called "tea-testers" (Russian tea merchants use the English word as it stands), who, when present on the Chinese frontier for buying the article, are obliged to test from 150 to 200 specimens of strong tea-infusion daily. True, they do not swallow the infusion, but all the same a slow intoxication appears in them. The symptoms are loss of appetite, constipation alternating with diarrhœa, failure of general nutrition, periodical epigastric pains, enlargement of the liver with subsequent atrophic cirrhosis, dryness and sallowness of the skin, hypochondriacal frame of mind, marked failure of memory, failure of sight (weakness of visual acuity, sometimes diplopia), failure of taste and smell. When they happen to contract syphilis, they are very slow to yield to the mercurial treatment. To make them more amenable, Dr. Smirnoff treats them before all by alkaline Essentük waters, with sulphur baths, and only afterwards passes to the specific mean. The results are often admirable.

Stomach Digestion.

Opportunities for studying gastric digestion through fistulous openings into the stomach are, says the *Med. Press*, thanks to modern surgery, more frequent than formerly. This is important, as the physiology of digestion, as understood at the present day, requires more than the classical instance of Alexis St. Martin to place it on a sound experimental basis. Such a case with experiments *ad hoc* is recorded in a revue scientifique by Von Herzen, of Lausanne. The subject was a man, æt. 28, on whom gastrostomy had been performed for occlusion of the œsophagus. The observations made were as follows: Bile always appears in the stomach during digestion, but generally only in the later stages. The amount of HCl amounts to 1.8 to 1.9 grm. pro litre; it increases during digestion, and reaches its maximum in the third hour. Sodium chloride appears rather to diminish the amount of acid. When the stomach was empty in the morning, but little pepsin was found,

and a large amount of propepsin; peptogen accelerated digestion. In the first hour, of a quantity of albumen introduced, 2 per cent. was digested without peptogen, 12 per cent. with it. In the second hour, 23 per cent. was digested without, 45 per cent. with peptogen. In the third hour, 51 per cent. without, 76 per cent. with peptogen. These results agree with those obtained by Schiff. Chloral, quinine sulphate, and above all, potassic iodide, retard digestion. The author would forbid red wine in disturbances of digestion, but would recommend bouillon and dextrine; blood fibrine is also indicated in many cases.

The Antiseptic Treatment of Summer Diarrhœa.

Dr. L. Emmet Holt thus concludes a paper in the *N. Y. Med. Jour.:*

From the foregoing discussion the following conclusions are drawn:

1. Summer diarrhœa is not to be regarded as a disease depending upon a single morbific agent.

2. The remote causes are many, and include heat, mode of feeding, surroundings, dentition, and many other factors.

3. The immediate cause is the putrefactive changes which take place in the stomach and bowels in food not digested, which changes are often begun outside the body.

4. These products may act as systemic poisons, or the particles may cause local irritation and inflammation of the intestine.

5. The diarrhœal discharges, *at the outset* at least, are to be looked upon as salutary.

6. The routine use of opium and astringents in these cases is not only useless, but, in the beginning particularly, they may do positive harm, since, by checking peristalsis, opium stops elimination and increases decomposition.

7. I do not deny nor undervalue opium in many other forms of diarrhœa than the one under discussion.

8. Evacuants are to be considered an essential part of the antiseptic treatment.

9. Experience thus far leads me to regard naphthalin and the salts of salicylic acid as the most valuable antiseptics for the intestinal tract.

Benzoin in Treatment of Ulcers.

In the *Russkaia Meditzina*, No. 35, 1886, Dr. A. Voskresensky, surgeon to the Fëodosïisky Regiment, highly speaks of benzoin (*Resina benzoës*) as a specific remedy for treating ulcers of every kind, but especially those which occur in emaciated, cachectic, and old persons. The remedy is largely used for the purpose by Russian peasants from the oldest times. The author employs it in the shape of a salve, prepared *extempore* of two drachms of resina benzoës, half on ounce of yellow wax, and half an ounce of lard. The ointment is spread in a moderately thick layer over a piece of linen, and placed on the ulcer. The latter must be previously irrigated with tepid water, and then dried with hygroscopic cotton-wool. The dressing is to be changed as a rule twice daily, but in cases of very large or old ulcers it is advisable to change it three times a day. A marked improvement becomes visible within a few days; torpidity of the ulcer, callosity of its edges, and its liability to bleed rapidly disappear: granulations assume a more rosy tint, and begin to discharge a thick benign pus; while there appears a whitish-bluish zone of the corium, which gradually spreads from the periphery towards the centre of the ulcer. So favorable an action of benzoin on ulcers is ascribed by the author partly to its disinfectant and antifermentative, partly to irritant properties.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A practical paper by Dr. J. M. Kershaw, of St. Louis, is upon the care of the mother and child in the lying-in room.

BOOK NOTICES.

Diseases of the Joints. By Howard Marsh, F. R. C. S. Small 8vo.; pp. 461. Lea Brothers & Co., 1887.

This volume belongs to the series of "Clinical Manuals for Medical Students and Practitioners," of which we have previously recorded the various issues. The present number seems to us hardly equal in merit to most of its predecessors. It savors more of a compilation, and draws less manifestly from the writer's independent observation. Nevertheless, it is an instructive little book, and describes the various diseases of the joints with considerable detail. A number of illustrations and one colored plate are added, and serve to set forth the text with advantage.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

PARALYSIS DUE TO COMPRESSION OF THE SPINAL CORD.

Paraplegia frequently is a symptom due to a myelitis, which may be produced by various morbid lesions, amongst which is compression of the cord. Dr. Strümpell, in Erlangen, has recently made interesting studies concerning the paraplegia produced by compression of the cord, especially when the latter is caused by accumulation of pus from diseased vertebræ or by other affections of the bony covering of the cord. In his investigations he made the important discovery that such a pressure, while giving rise to paralysis of both lower extremities, produces this palsy by mechanical action and without the development of any inflammatory process. These are the cases where after death no part of the spinal cord shows any degeneration, and also those cases belong here where after absorption or otherwise removal of the compressing substance, the paralysis disappeared and motion returned as good as ever. In this way the cases may be explained where disease of the vertebræ is accompanied by paraplegia which ceases as soon as the morbid state of the vertebræ has become cured.

In Pott's disease it is the spontaneous peripachymeningitis which brings about a cure and leads to the absorption of the pus. When the curative inflammation has reached such a degree as to have resulted in perfect immobility of the diseased vertebræ, the pus is sometimes absorbed with surprising rapidity, and experience has proved that this favorable state of affairs is occasionally brought about with great suddenness by powerful emotion, which seems to be a great factor in stimulating absorption of inflammatory products. Such cases are often reported as complete faith-cures, and we ourselves know of one case where scrofulous disease of two dorsal vertebræ had produced an accumulation of pus which pressed upon the cord at that place and caused paraplegia. The cessation of the pain on motion and various other symptoms had demonstrated the consolidation of the diseased vertebræ, which under treatment had occurred with very little change in the position and appearance of the spine; but the paralysis of the lower extremities still remained, until one day, under the influence of the powerful emotion caused by the excitement attending a faith-cure, suddenly the paraplegia left and the patient could walk. Any other excitement might have resulted the same way, though the palsy would have slowly disappeared under any conditions as soon as the mechanical ob-

struction was removed—here the accumulated pus.

On account of the grave prognostic points involved, the observations just recorded are of great importance; as above, the fact is elicited by Strümpell that the compression may result in paraplegia, due to transient mechanical means and remediable without leaving a trace behind in the cord itself, as this need not be affected at all in such cases.

COLD WATER IN FEVERS.

Thirty or more years ago physicians starved their fever patients, and were opposed to the use of cold drinks in these diseases. The writer of this remembers a case that he saw in consultation with a colleague some twenty years ago. The poor patient lay there in an apathetic condition, and the end seemed to be near. The movements of his tongue and lips appeared to indicate great thirst; the lips seemed parched. On close inquiry, he discovered that the patient had received no nourishment of any kind, and no fluids, neither water, nor milk, nor tea, nor any other beverage, for the last six days at least. The attendants only remembered some warm tea that he had taken just one week previously, and he had since refused taking medicine—for the last four days, nobody had made an attempt at least of administering any to him. The attending physician later admitted that he had completely forgotten to inquire about food or drink, and perhaps the more so as he had considered the case hopeless for more than a week. The story seems improbable to-day. He yet remembers the eager haste with which the poor sufferer swallowed the small quantity of cold water he gave him. For nearly an hour he handed him every few minutes alternately cold water, milk, bouillon, whisky with water, and thin oatmeal gruel, and the eager haste did not cease until near the end of the hour, when he gave directions for feeding him every two hours with some fluid nourishment, and for the administration of about two tablespoonfuls of water every five minutes, while every half an hour a teaspoonful of whisky was added to it. For fully four days the patient each time showed the pleasure he felt on receiving the food or drink; he greatly improved, and had the first healthy sleep the fifth night, after which he was fed in the usual manner, and given to drink when he asked for it. He completely recovered.

Though the starving system has ceased, there is danger of our falling into the opposite error, and especially the administration of large amounts of cold drinks seems to be attended with some risk. Dr. Glax, of Graz, (*Deutsch. Med. Zeit.*, December 14, 1886,) has found that drinking of profuse quantities of cold water produces an increase of temperature. The water thus imbibed in great amount by patients suffering with fever is not at once all absorbed, but a retention occurs, which ceases only with the disappearance of the fever, when a greatly increased diuresis expels the fluid. With this accumulation of fluid in the body, the increase of temperature goes hand in hand, so that we may influence the fever and reduce the heat by limiting the water supply.

An explanation of the modus operandi may be found in the following: When the tonus of the blood-vessels is lowered, the introduction of large quantities of water into the system gives rise to a retarded capillary circulation, so that the time during which the minute particles of tissues are in contact with the blood is prolonged, a fact necessarily augmenting oxidation, while the moment the introduction of water is limited the opposite takes place, and the capillary circulation is quickened, and oxidation and with it the bodily heat diminished.

COMPARATIVE PATHOLOGY.

It would be a long step in advance if we could reach some broad generalization which would correctly express the difference between health and disease. Such a generalization would have to take account of many facts not contained in the pathologies we are accustomed to study. It would have to go beyond the human organism and include that of all animal forms; more than this, it would be incomplete if it omitted the vast number of organic existences which make up the vegetable kingdom; nay, it could not stop there, for recent researches by learned and competent observers, especially in Italy and France, have shown beyond question that wholly inorganic bodies, such as crystals, are subject to diseases which they resist or attempt to overcome by processes of repair and substitution, strangely analogous to those seen in man.

Pathology therefore will not be studied successfully until it is studied in its broadest horizons. Possibly its secrets will be found to lie nearest the surface in its simplest expressions. As the biologist turns to the least complicated forms of life as the most promising paths for his pursuit, so the pathologist will probably find that the diseased condi-

tions of minerals and vegetables will be his most suggestive guides to understanding the perturbations of the complexity of man's economy. The near future bids fair to furnish some interesting revelations in this direction.

Notes and Comments.

Pilocarpine in Datura Poisoning.

Dr. Roth (Nagy Bajour, Hungary) was summoned to a little girl, aged 4, whom he found quite unconscious. The pupils were dilated, the face and the rest of the body were swollen as in dropsy, and covered with a rash resembling that of scarlatina. The little patient was uneasy and restless, and ground her teeth. Pulse 146, slight and weak; respirations, 40; temperature 39° Cent. (102.2° Fahr.). Her bowels had not been opened, nor had she passed urine since the commencement of the attack. A local medical man had prescribed fifteen centigrammes of antimony; but her father, who was a chemist, being persuaded that this would do no good, gave her a solution of sulphate of copper. She vomited a large quantity of the fruit of the datura stramonium. Dr. Roth, remembering how Professor Purjeck had cured a case of atropine poisoning by means of subcutaneous injections of pilocarpine, administered half a centigramme of that drug in twelve hours. This produced neither salivation nor perspiration, and there was no improvement. After a centigramme had been injected, however, the rash and the swelling began to subside. A quarter of an hour later, another centigramme was injected, and the child's condition improved still more. The injections were continued, and at six o'clock the pupils had become almost normal. Pulse 120; temperature 39.7° Cent. (102.9° Fahr.). The patient spoke with ease, and said she felt hungry. An hour later, as there was still no perspiration, another half centigramme was injected. Salivation and perspiration ensued, and rapid recovery followed. Altogether, five grammes and a half were administered. Dr. Roth considers that this dose was necessary to neutralize the poison.

The Heart and Large Abdominal Tumors.

At a recent meeting of the Biological Society of Paris, M. Pierre Sébileau read a paper on the heart and large abdominal tumors. Whilst house surgeon at the Salpétrière Hospital in Dr. Terrillon's ward, he was struck by the frequency of cardiac complications in women suffering from large tumors of the abdomen. Among forty-six cases of that kind the condition of the heart was not noticed in eighteen; in eleven it was unaffected, but in seventeen there was functional disorder. Among these seventeen there were thirteen cases of cystic disease of the ovary, four of solid tumors of the ovary, and one uterine myoma. In the eleven cases in which there was no cardiac affection there were six of ovarian, or parovarian, cysts, three of uterine myoma, one of chronic encysted peritonitis, and one of large hydatid cyst of the liver. The conditions noticed were hypertrophy of the left ventricle, or dilatation of the same cavity, according to the period of the affection at which the patient was examined. Frequently both symptoms were co-existent. Hypertrophy is difficult to recognize, but dilatation produces mitral regurgitation. A souffle with the first sound is a constant symptom, systolic friction-sound is rare, and the pulse is slow and feeble. The heart may be affected by disturbance of the general abdominal circulation from pressure; by increase of area in the circulatory system; by secondary renal lesions resulting from the compression of the ureter; by reflex spasm of the general capillaries, or by deterioration of the blood. Pressure on the aorta, however, is in all cases the cause of the existing hypertrophy, or dilatation.

Diagnosis of Tumors of the Bladder.

At the French Congress of Surgery, M. Guyon made the following statement concerning the diagnosis of tumors of the bladder. Hæmaturia is a very important symptom, on account of its duration, its frequent recurrence, and its being easily provoked by the mere passage of a bougie. This serves to distinguish a tumor of the bladder from a tumor of the kidneys. The latter are recognized by the increased size and mobility of the kidneys, the concomitant varicocele frequently observed, and the cylindrical clot peculiar to hæmaturia and colic. A neoplasm in the wall of the bladder is discovered by examining the rectum and the bladder. Another important symptom is the increased size of the bladder. The introduction of a catheter does not reveal the presence of a tumor, but in certain cases may afford valuable indications. It has been suggested that perineal incision should be employed in order to determine the exact spot to which the growth is attached. M.

Guyon does not recommend this, except in cases in which the tumor causes complications such as cystitis, retention of urine, or any kind of disturbance in the urinary function. In such cases the operation should be done rapidly. M. Guyon prefers hypogastric to perineal operations, and uses the actual cautery in the lower part of the bladder. He performed eighteen operations on fifteen patients, and discovered thirteen malignant and two benign tumors.

The Leaves of Cloudberry as a Diuretic.

In the *Russkaia Meditzina*, No. 34, 1886, Dr. Ivan Troïtzky, of Smolensk, emphatically recommends an infusion of the leaves of cloudberry (*Rubus chamæmarus;* Russ., *moroshka*) as an excellent diuretic remedy suitable in dropsies of every description (and extensively employed as such in the Siberian popular medicine). To prepare the infusion, the author puts (in the evening time) two drachms of the dried (not too old) leaves into a teapot, pours over the leaves two teacupfuls of boiling water, and keeps the vessel during the night in a very warm place to use the infusion in the course of the next day (a cup in the morning, another in the evening). "Its taste is not very nasty, and becomes the less nasty the more the patient is habituated to the infusion." The author gives at length his own case. He is eighty years old, and has suffered from "œdema pedum" for more than ten years (chiefly every spring, but often also during summer, when the latter happens to be wet). At first he used Adonis vernalis and other diuretics, as well as elastic stockings, and obtained some benefit from them; but afterwards the said means ceased to bring any relief. Hence, about five years ago, he was compelled to resort to the infusion of cloudberry leaves, massage, and elastic bandage. The results were most satisfactory on every occasion. Under the use of cloudberry, the daily amount of urine always rises to 54, 60, 72, 83 ounces (to sink, after discontinuing the drug, to 55, 45, 40, 38 ounces). Each time a month's treatment of this kind proves sufficient to remove œdema and pain.

Paraffin in Surgery.

It is perhaps not so well known in the profession as it ought to be, that paraffin is a most useful material in surgery, in many cases superseding plaster of Paris. It answers admirably for splints, and for jackets for young children suffering from spinal disease. The advantages of it are that it is clean, light, is capable of being moulded while it is soft, and sets rapidly by pouring cold water on it. It must be procured with a melting point of 130°. When ordering it it is necessary to specify the melting point required. The mode of using it is this: The paraffin is melted by placing a tin can containing it in a pot of boiling water. A muslin bandage well sprinkled with iodoform is put on the limb, or other part to which the paraffin dressing is to be applied. Muslin bandages loosely rolled are allowed to soak in the paraffin for a few minutes. If much support is required, a piece of cotton-wool is also soaked in the paraffin. This is placed where most stiffness is wanted, and the bandages applied as for plaster of Paris dressing. They may, however, be drawn tight as the paraffin shrinks from the limb in cooling. Cold water is then poured on it, and the limb held in position till the paraffin has set. When a bone tends to project, it can be kept in position by the finger till the paraffin has set. The hole left by the finger can then be filled up with some melted paraffin. In cases of compound fracture, the paraffin has the great advantage of not being affected by the discharge from the wound.

Antifebrin in Typhoid Fever, Pneumonia, and Sore Throat.

In a prelimtnary note in the *Russkaia Meditzina*, Nos. 44 and 45, 1886, Dr. Trüsheinikoff, of Odessa, describes his experience in regard to the use of antifebrin in abdominal typhus (four cases), croupous pneumonia (two cases), and angina. His general conclusions are these:

1. Antifebrin rapidly lowers the febrile temperature, which falls to the standard within two hours, to keep at the level for one and a half to two hours; and then, after a slight rigor with coldness of the limbs, to rise again and reach the original height.

2. The rapid fall and rise of temperature does not manifest any injurious influence on the heart, the pulse beating slower or more frequently according to the decrease and increase of the temperature, but never showing any other deviation from the normal.

3. Even in the dose of from two to five grains, antifebrin produces slight perspiration, the formerly dry skin becoming moist.

4. The drug acts also locally, since the tongue, which was formerly dry and thickly coated (*e. g.* in typhoid patients) becomes moist and red, and stools normal. Administered in the shape of a gargle (one scruple of the drug to five ounces of water), anti-

febrin soothes, and ultimately cures, inflammation of the fauces and pharynx.

Cantharides in Hydrophobia.

According to Dr. Lukomsky, of Prilüki (*Russkaia Meditzina*, No. 42, 1886), the Little Russian peasantry treat domestic animals bitten by a rabid dog or wolf, by administering dry cantharides, divided in three or four parts, in a bread pill, and simultaneously a decoction of *drok* (*Genista tinctoria*) is given. The treatment lasts two or three days, and, as a rule, proves quite successful. About forty years ago the author was called to five peasants who had been just before bitten by a rabid wolf. Having washed out their wounds, he applied unguentum cantharidum and administered internally half a grain of powdered cantharides with one grain of calomel twice daily, and a decoction of *drok* and root of wild elder-tree (*Dikaia büzina*), two glassfuls a day. Suppuration was kept up for three weeks; the internal treatment continued two weeks; cantharides, however, were discontinued each time as stranguria and scalding in the urethra appeared, to be again resumed after the disappearance of those symptoms. All four patients treated after this plan remained well, while the fifth, who had refused to take cantharides, died from hydrophobia. The same method of treatment was applied with equal success by Dr. Lukomsky in three other cases of bite by rabid dogs.

How to Abort a Felon.

Dr. John T. Metcalf writes to the *Boston Med. and Surg. Jour.*: "My father was a medical man, who graduated from the University of Pennsylvania in 1816 or 1817. In 1839 I learned from him that a felon could, if seen early enough, be made to abort by wrapping the finger-end with narrow strips of adhesive plaster. When pus had been formed, I learned twenty years ago, from a country doctor, that immediate relief and speedy cure would follow the gentle, slow separation of the nail from its envelope by means of a penknife blade, not too sharp, at the point nearest the seat of greatest pain. Very soon a drop of pus shows itself, and relief comes. I am aware that the plan described is known to many medical men. It was not known to me at the time referred to, when the country doctor showed me how to treat a paronychious patient, whose finger I was about to lay open by the 'free incision down to the bone,' taught in the lessons of my great masters."

Disadvantages of Milk Diet.

At a recent meeting of the Société Médicale des Hôpitaux, M. Debove presented a patient, who is in good health at the present time. His case offers a striking example of the disadvantages of a milk diet. Two years ago he showed signs of alcoholic gastritis, followed by symptoms of simple ulcer of the stomach. A milk-diet was adopted, and the patient finally took as much as eight litres a day. After a certain time he grew weak, and reached such a condition of cachexia that he was unable to stand. M. Debove washed out the stomach, removing two and a half litres of liquid. This was repeated, and the patient was put on a diet consisting of one and a half litres of milk, with a little meat. The patient lost 36 pounds under a milk diet. Since M. Debove's treatment has been adopted, he has gained 30 pounds, and is now perfectly well. The excessive dilatation of the stomach was due to an excessive milk diet.

Cancer and its Treatment.

Dr. Blenkinsop made a passing reference to the pathology and causation of cancer before the Harveian Society of London, and then dealt with the purely medical aspect of the question, both in regard to internal forms of the disease, and its general constitutional treatment. He leaned to the belief in a cancerous diathesis, and argued in favor of preventive measures in suspected constitutions. He thought that efforts should be made to test the value of all remedies which presented a reasonable prospect of success, and related details of four cases in which lime salts appeared to have had a beneficial effect. He assumed that the deposit of lime salts in the vessels gave rise to atheromatous and calcareous degeneration, and so lessened the supply of blood to the cancerous tissues. Cretaceous preparations derived from the animal kingdom, for example from oyster-shells, appeared to derange the stomach less, and to be more readily absorbed.

Cocaine in the Incoercible Vomitings of Pregnancy.

Cocaine has lately come into use for the incoercible vomitings of pregnancy, says the *Boston Med. and Surg. Jour.*, and in several cases reported by Weiss, Engelmann, Holtz,

and Bois, it seems to have given good results. Weiss prescribes a teaspoonful every half hour of a solution containing fifteen centigrammes of hydrochlorate of cocaine in one hundred and fifty grammes of water. Engelmann and Holtz use a three per cent. solution in ten to thirty-drop doses, while Bois applies to the neck of the uterus, night and morning, a pomatum in which one centigramme of cocaine is incorporated with fifty grammes of vaseline. Fraipont prefers the hypodermic method, injecting under the skin a Pravaz syringe full of a four per cent. solution, and claims signal success in other forms of obstinate vomiting, as well as in the vomitings of pregnancy.

Antipyrin in Migraine.

In the *Meditzinskoie Obozrenie*, No. 23, 1886, Dr. Vladimir Sprimon, of Borisoglebsk, writes that he uses antipyrin in all cases of hemicrania, and, as a rule, obtains excellent results. Given at the height of a fit, the drug only partially relieves pain, but does not shorten the duration of symptoms (especially when the patient remains on his legs all the while). But when administered during the period of prodromal phenomena, antipyrin almost invariably cuts short the paroxysm within an hour, and allows the patient to immediately resume his occupations. The dose required is one scruple. In delicate persons, or in those liable to giddiness, it is better to divide the dose in two parts, and to give the second portion (if necessary) about half an hour after the first.

Death from Chloroform.

The death of a man aged fifty-four, while under the influence of chloroform, administered for the purpose of performing an operation on a long-standing disease, recently occurred at Bradford, England (*Brit. Med. Jour.*, January 15, 1887). The evidence given at the inquest showed that every precaution was taken, and that an examination of the heart before the administration revealed no evidence of disease. An ounce of brandy was administered three-quarters of an hour before the administration of the chloroform. Immediately on the completion of the operation the heart's action was found to have ceased. It was stated that the deceased had successfully undergone a similar operation twenty-five years before.

Ichthyol in Erysipelas.

Dr. Nussbaum, of Munich, has recently obtained strikingly successful results in traumatic erysipelas by the use of an ointment composed of vaseline with 10 per cent. of ichthyol, a chemical substance rich in sulphur, obtained from mineral oil, which was introduced by Dr. Unna a few months ago, and which was found useful by Dr. Dubelir, of Moscow, in acute and chronic rheumatism (see the *Lancet*, Oct. 2, 1886), both as a medicine and as an external application. Dr. Nussbaum found, as indeed Dr. Dubelir also remarked, that the ichthyol had an irritating effect on the skin, so that it could not well be borne for more than three days; but as this was long enough to effect a cure in all the cases, no difficulty on this head arose.

Lymphoderma Perniciosa.

Kaposi (*Wien. Med. Jahrb.*) describes under the above name a new disease which he observed in a woman, thirty-nine years of age. On admission to hospital the patient was pale, had swellings of the cervical and inguinal glands, nodular infiltration in the palm of the left hand, as well as flexor surfaces of both forearms; and the clinical symptoms of a universal eczema. In the face, neck, and upper part of the breast the infiltration of the subcutaneous tissue was so great as to produce the appearance of leontiasis. The infiltration became nodular, and gave rise to serpiginous ulcers. The spleen enlarged, the leucæmia increased, and the patient died. The author regards the disease as lymphatic in its nature.

Pulverized Spleen in Chlorosis.

The German medical papers quote some observations made by Dr. Predazzi at Prof. Maragliano's request, on the value of treating chlorotic patients with an emulsion of pulverized spleen, bitter almonds, and brandy. In the five cases in which this was adopted, rapid improvement took place both in the general condition of the patients and in the physical signs; that is to say, the number of red blood-corpuscles was increased, as also the arterial tension and the body weight. The author does not attempt any explanation of the action of this singular remedy. The quantity of "polp. splenic." given daily was about five ounces, and it was ordered at meal times.

Antifebrine in Typhoid.

Antifebrine has been used a great deal in Professor Kotovshcheski's clinic in Kazan in typhoid fever cases with good results. After

a single four-grain dose, the temperature sank in the course of an hour 0.9° to 0.2° C., the reduced temperature persisting for from an hour and a half to three hours. It was found that by repeating these four-grain doses every two hours the temperature could be kept at the normal point all day. The frequency of the pulse was at the same time diminished, and its tension increased. The excretion of urea was also augmented. The patients liked the drug, and no ill effects were ever observed from its use.

Salicylic Acid in Food.

M. Vallin has presented a report to the French Government on the employment of salicylic acid in articles of food, in which he states that medical observation has established that even small quantities of salicylic acid, or its derivatives, if taken constantly, are capable of affecting the health of certain subjects who are peculiarly susceptible to the influence of this drug, as also the health of aged persons and those whose whose renal and digestive organs are not perfectly sound. He consequently advises that the addition of salicylic acid and the salicylates, even in small quantities, to solid and liquid articles of food, should be prohibited.

Intestinal Calculi.

Dr. Hockenhull reports in the *Atlanta Medical and Surgical Journal* a case of a boy who was suffering from tenesmus. Examination of the rectum showed a mass of small hard stones, forming a complete wall, obstructing and distending the bowel. The stones were of a black color, and of a hard, flinty nature, and varied in size from that of a pea to that of the end of the little finger. According to the father's account, the total number of stones extracted at the time and passed subsequently was four hundred and two.

Correspondence.

Paris Letter.

(FROM OUR OWN CORRESPONDENT.)

The New Professors of the Paris Faculty. Acetanilide. Iodoform in Variola and Erysipelas. Pilocarpidin. Salicylate of Bismuth. Vesication by Hydrate of Chloral. Magnesia for Warts.

EDS. MED. AND SURG. REPORTER:

The Paris faculty, as now constituted, is almost entirely composed of new men. When I first came here, in 1876, the older men were in all the principal chairs. Sappey was Professor of Anatomy, Béclard of Physiology; Gavarret, of Physics; and Chauffard, Medicine. Men who had acquired an European reputation also accupied the clinical chairs: Germain Sée had just taken Béhier's place at the Hotel Dieu and Gosselin and my own dear master, M. Hardy, were at the Charité.

It may not be uninteresting to recall, even to a foreign auditory, the distinguishing characteristics of these notable men, who are now just finishing their active career as professors. I will speak only of their personal peculiarities; their scientific attainments are known to your readers through medical literature.

First, the venerable and revered Sappey. No man was more respected by the students. When his venerable figure appeared in the lecture-room no uproarious and aggravating applause greeted or disturbed him. I have seen the ever popular and lamented Professor of Chemistry, Wurtz, check such applause by a comical upward deprecating look at the boys. Sappey, undoubtedly one of the ablest anatomists of his time, was a courtly old gentleman of the old school, whose only regret in life, I think, has been that he was never a practical chirurgien des hopitaux. It seems to be an unwritten law at Paris that the man who aspires to and is considered worthy of the chair of anatomy should not enter the surgical service of the hospitals or attempt to acquire renown as a surgeon. Such has been the case with M. Farabeuf, who succeeds M. Sappey; he has been unsuccessful at several concours for the hospital service. Farabeuf is a comparatively young man, full of energy and push, rather nervous withal, but certainly the ablest anatomist at present in Paris. Gavarret, the lately deceased Professor of Physics, was a relic of by-gone days; his name and some of his experiments were connected with the early history of modern physics. His successor, Gariel, who originated the idea expressed in Barnes' uterine dilators, has so long lectured in Gavarret's place that it seems natural to see him occupy the chair. Dieulafoy, one of the newly-appointed professors of medicine, is, perhaps, best known in the United States as the inventor of the aspirator which bears his name. He is quite a young man, a very able clinical teacher, and to him undoubtedly belongs the credit of originating, or at least vulgarizing, the use of the aspirator for the removal of fluid accumulations in the chest and elsewhere.

The hospital service is also rapidly changing. Broca, the portly and majestic surgeon of the Hôpital Necker, is dead; the accoucheur Dépaul is dead, and Gosselin and Hardy have just been retired by limitation of age. Gosselin was always on duty as early as eight o'clock in the morning; he very rarely missed his time, and his short, rotund figure and rosy face became very familiar to me in those early student days. A very kindly old man too, and one who rarely undertook operations of doubtful utility to the patient.

Then at nine o'clock at the Charité came M. Hardy, probably the best clinical teacher of the present day in Paris. Although his name is almost entirely associated with cutaneous pathology in connection with Bazin long since deceased, M. Hardy has been for many years one of the four professors of clinical medicine of the faculty of Paris. This personality is perhaps the most striking of any of the retired professors, tall and spare, with iron-gray side whiskers and a rather vulgar cast of countenance; his students voluntarily compared him to a coachman. His clinical lectures were always crowded and deservedly so, for they were the most practical delivered at Paris.

His confrère, Germain Sée, who fills Trousseau's chair at the Hotel Dieu, is a man of different stamp. He is of Jewish descent, as are also Charcot, Hayem, Marc Sée, and several other prominent members of the Paris faculty.

His lectures are always good, but hardly bear the stamp of originality, and his service is hardly conducted in a manner to benefit a student who desires to learn. Germain Sée says very little during his visit, and most of what is done bears the stamp of selfish attention to his own personal interests. During one vacation he was replaced by Grancher, whose name has become connected with that of Pasteur in his inoculations of attenuated rabic virus. Grancher is undoubtedly one of the ablest clinical instructors of the faculty.

The obstetricians also are all changing. Depaul is dead, but is worthily replaced by Charpentier. Just at present Pajot, the most popular man in the faculty, is retiring at the ripe age of seventy. I attended Pajot's lectures largely about ten years ago, when his auditory always filled the miserable and hard-seated ancient amphitheatre of the faculty. His lectures, like those of most professors of this branch, were replete with anecdotes, containing in his case rather more of the *sel gaulois*, which Victor Hugo extols so much, than could be well appreciated or liked by transatlantic ears. Pajot was then a notable example of the *jeunes vieux*, satirized in some of Eugene Sue's novels, and stigmatized by George Augustus Sala in his book "Paris Herself Again." He was at that time over sixty years of age, but he was habited in a youthful, jaunty costume, could play a good game of billiards, and lived altogether the life of a man about town.

In fact, almost an entire change is taking place in the personnel of the faculty, and the visitor to the Exposition of 1889 will find a different body of men from those constituting that scientific body at the time of the last Exposition in 1878.

Acetanilide.

M. Dujardin Beaumetz has been recently experimenting with acetanilide, a new product of moderate cost. It appears to have a special calmative action in bulbar disorders. It has proven of much benefit in the darting and lightning pains of ataxia. It has been also of signal benefit in one or two cases of epilepsy, where bromides had given no results, or where bromism had prevented their use.

Iodoform in Variola and Erysipelas.

M. Colleville has recently made use of an unguent containing iodoform as an application to the skin in small-pox. He claims for it an anæsthetic action in relieving pain, and avers also that it seems to act in preventing the formation of crusts. M. Decés, of Rheims, confirms the assertion of M. Colleville, and finds that the same application is of very great utility in erysipelas, as it causes resolution of the swelling and inflammation in a few days.

I can myself speak of the benefit obtained from an ointment containing iodoform (ʒj to the ℥j of the simple cerate) in the treatment of ervsipelas. I was first led to use it as a set-off to a quack-salve, or rather grease, which had a great reputation in my neighborhood. I have invariably found it a good application, soothing the pain, inducing resolution, and preventing the spread of the inflammatory exudation.

Granular Conjunctivitis.

M. Jules Rouquette, physician to the college, schools, and public institutions in Bône, Algeria, where granular conjunctivitis is very prevalent, gives the following treatment as the most beneficial in his practice:

1. At the debut of the affection, apply thoroughly the following solution:

℞. Argenti nitrat., 1 gram.
Aquæ distill., 50 grams. M.

Neutralize with a saturated solution of salt applied afterwards with a camel's hair brush.

2. When the disease is of longer duration, touch each granulation separately with the solid stick of nitrate of silver, using the neutralizing solution afterwards.

The next day bathe the eyes frequently with warm chamomile tea.

Subsequently apply to the conjunctival membrane with a brush morning and evening the following solution:

℞. Cupri sulphat., 1 gram.
Glycerini pur., 10 grams. M.

After fifteen or twenty days this treatment gives remarkable results.

If necessary, a second application of the solid stick can be made, and if the pain after such application is severe, a one per cent. solution of cocaine can be applied with a camel's hair brush.

Pilocarpidin.

M. Meyer has recently made a communication in the *Archiv. für Experiment. Pathol.*, relative to this alkaloid, obtained from jaborandi.

It appears to have the same properties as pilocarpin, but is much weaker, and its toxic effects are not so marked, probably on account of its more rapid elimination from the system.

M. Solger (*Deutsche Med. Zeitung*) has made use of salicylate of bismuth in diverse forms of chronic diarrhœa and intestinal catarrh. He considers it of especial value in the diarrhœa of phthisis and typhoid fever, where the astringent properties of bismuth conjoined with the antiseptic value of the salicylic combination are particularly needed.

Hydrate of chloral, finely powdered over adhesive plaster, and applied after a slight exposure to heat, is strongly recommended for blistering purposes by M. Ivanowsky (*Wratsch*, 1886, p. 292). The application is said to produce vesication after fifteen to twenty minutes.

M. Cobrat, in the *Lyon Medical*, strongly recommends the internal administration of magnesia to young children suffering from warts. He has obtained excellent results in several cases by the administration twice daily of fifteen centigrams of magnesia.

New York Doctors and the Newspapers.

Eds. Med. and Surg. Reporter:

Did you live in this State, you would the better know why the names of some of our distinguished surgeons and physicians appeared in the newspapers after some ordinary operation had been made, or they had been called as a consultant to see some man distinguished for his wealth or military prowess.

To us the cause is well known, to wit: *he is invariably opposed to the National Code of Ethics*, and is a member of the "new" or "no code" faction, a small minority of the profession in the State. How strange it is, that all these notices are published without the knowledge, consent, or *pay* of the individual eulogized! D. Colvin, M.D.

Clyde, N. Y., February 7, 1887.

News and Miscellany.

A Prize Essay on Hay Fever.

The Chairman of the Committee on Scientific Facts, of the United States Hay Fever Association, asks leave to submit the following to the members, and to the medical fraternity, and to all who are interested, whether as sufferers or students of this increasing malady:

At its last meeting, September, 1886, at Bethlehem, N. H., the Association decided to offer a prize for the best essay from a competent source, preferably a physician, on some question relating to *æstivis*, or hay fever. The amount is necessarily small; but, as the accepted essay will be published in the Association's report, when the extent of its circulation, and the character of those whom it will reach shall be considered, it is thought that the successful treatise will give to its author a reputation worth the effort.

In order to carry out the above the following is announced officially:

1. Subject of the essay, Hay Fever. (*a*) Its pathology. (*b*) The predisposing, and the aggravating causes. (*c*) Advice to the sufferer.

2. The essay not to exceed *four thousand words*, and to be as practical and non-technical as possible.

3. The manuscripts to be received at the office of Samuel Lockwood, Freehold, New Jersey, not later than April 30, 1887.

4. Each manuscript to have a motto under the title, and to be accompanied with a sealed letter containing said motto, also the name and address of the author. These letters not to be opened until after the award is decided.

5. The prize to be $25. The accepted essay to be published immediately in the Association's annual report, one hundred copies to be given the author.

6. The Committee of Award: Samuel Lockwood, Chairman of Committee on Scientific Facts; Frank B. Fay, President U. S. H. F. A.; Charles C. Dawson, Secretary U. S. H. F. A.

SAMUEL LOCKWOOD,
Chairman of Committee on Scientific Facts.
Freehold, N. J., Jan. 15, 1887.

Vaccination in Peru.

It is satisfactory to learn, from a recent number of *El Monitor Médico* (Lima), that some steps are being taken to persuade the Government of Peru to establish compulsory vaccination in the Republic. At present the only place where the compulsory system is in force is in Lima itself, where it has been established as a local enactment by the municipality. Provincial vaccinators find the greatest difficulty in keeping up supplies of lymph, and are frequently obliged to apply to the Lima authorities, who, at the desire of the Government, assist them as far as possible. The Free Academy of Medicine has recently caused the whole matter to be looked into, and a report to be drawn up by a committee of its members. They say that the frequent epidemics of small-pox and the numerous cases that are constantly occurring in most of the towns of Peru are accountable for a large part of the present high rate of mortality; that the experience of all other countries shows that the only way to make vaccination really effective is to render it universal by compulsion, which cannot be carried out without arrangements for supplying lymph to all requiring it; and that the best way of doing this is to confide the charge of a central establishment to a scientific body—that is to say, to the Academy of Medicine. It is remarked that the neighboring republic, Chili, established compulsory vaccination in 1884, and has an institute of animal vaccination in Santiago which is subsidized by the Government to the extent of $3,500 a year.

Disease Among the Indians.

Dr. Washington Matthews, surgeon in the United States Army, has made a valuable contribution on the causes which are at work in carrying off the Indians of our country. One of the most important of these he finds to be consumption. From the census of 1880 we learn that, while the death-rate among Europeans is 17.74 per thousand, and that among Africans 17.28, the death-rate among the Indians is no less than 23.6. In diarrhœal diseases the Indian death-rate is not greatly in excess of that of the other classes. Measles gives a mortality of 61.78 per thousand, but it is under the head of consumption that the difference between the Indians and the blacks is most conspicuous; the rate among the former being 286 as compared with 186 among the latter, while among the whites it is but 166 in the thousand. Dr. Matthews finds that where the Indians have been longest under civilizing influences the consumption rate is the highest; meaning by the term "consumption rate" the number of deaths from consumption in a thousand deaths from all known causes. Thus the rate among reservation Indians in Nevada is 45; in Dakota, 200; in Michigan, 333; and in New York, 625.

Effect of Freezing on the Typhoid Germ.

Dr. John S. Billings, U. S. A., writes as follows to the *Sanitary Engineer* of January 29, 1887:

It is well known that freezing water does not destroy the vitality of all living organisms contained in it, although it does appear to kill some of them. To settle the question as to the effect of freezing on the bacillus of typhoid, I have had the following experiments made:

January 10, 1887. Five cubic centimetres of sterilized water in a test-tube were inoculated with typhoid bacillus and exposed to the outer air during the following night at a temperature of about 10° F. It was found solidly frozen in the morning.

January 11, 2 p. m. This frozen mass was thawed, and from it there were inoculated one agar and three gelatine tubes.

January 13, 10 a. m. There is decided typical development of the typhoid bacillus in the agar tube and in two of the gelatine tubes.

Evidently, therefore, the vitality of the typhoid bacillus is not destroyed by freezing.

The Bacillus of Typhoid Fever.

An inquiry lately made by Dr. Brouardel into the circumstances of an outbreak of typhoid fever at Compiègne led to the discovery of a bacillus in the water which the victims used for drinking. This is the well-known bacillus which, when cultivated in gelatine, multiplies in colonies; and a similar germ was found in blood drawn from a patient suffering from enteric fever. It had probably come from the water closets, which were established in a sandy porous soil; beneath this was a layer of compact clay,

through which the water drained to the well. The bacilli were much more numerous in the infiltrations of the sandy layer, a purification apparently taking place there which left the well water limpid, without any impure taste. This fact proves that in the filtration of sewage-water through the soil, certain organic matters may be retained, whilst dangerous bodies are allowed to pass.

Professor Johann Rudolph Ranke.

The University of Groningen is just now mourning the loss by death of the much respected Professor of Surgery, Dr. Johann Rudolph Ranke, who, though a foreigner, seems to have endeared himself to all classes of the people. For the last eighteen months he had suffered from the effects of blood-poisoning, which had caused him continual severe pain; but he stuck most heroically to his work to the last, teaching from his bed students who were about to present themselves for examination, and, on days when he was somewhat better, going in a bath-chair to the university or hospital. Only three days before his death he performed an important operation.

Bucks County Medical Society.

The midwinter meeting of the Bucks County Medical Society was held last Monday in Bank Hall, Quakertown, Dr. J. J. Ott, of Pleasant Valley, presiding. After the usual routine business Dr. A. M. Cooper, of Point Pleasant, read an article on albuminuria, detailing the diagnosis and treatment of several obscure cases. The discussion was carried on by Drs. Thomas, Moyer, Cawley, and Ott. Dr. William E. Ashton, of Jefferson Medical College, Philadelphia, then delivered an illustrated lecture in gynæcology. Four new members were added to the society.

Death of Madame Trelat.

The death is announced from Paris of Madame Ulysse Trélat, the wife of the late Dr. Trélat, Governor of the Salpêtrière Hospital. Madame Trélat, whose life has been largely spent in charitable work among the deserving poor, and who took an active part in the creation of technical schools for girls, has left $40,000 to the poor of Paris. The rest of her fortune she leaves to schools and other institutions of public utility.

Vegetable Fibres in the Intestines.

At a recent meeting of the Société Médicale des Hôpitaux, of Paris, M. Laboulbène showed some worm-like bodies which had been passed by a cachetic child of twelve. They proved to be macerated vegetable fibres twined round in the intestine, and subsequently expelled in the form of scybala.

Personal.

—Dr. Wm. E. Ashton, assistant demonstrator of obstetrics and clinical assistant of diseases of women at the Jefferson Medical College, delivered, last Monday, before the regular meeting of the Bucks County Medical Society at Quakertown, a lecture upon "The Diagnostic Value of Palpitation and Auscultation in Obstetrics."

—Dr. Richard J. Levis is expected home in the spring. He has been "doing" Egypt.

—Dr. D. B. Birney, late of the Presbyterian Hospital, is now connected with the medical staff of the Philadelphia Dispensary.

—Thomas K. S. Morton, M. D., late of the Pennsylvania Hospital, sailed for Europe recently. Dr. Morton intends to pursue his studies in Berlin during the ensuing summer, and return to this city in October to resume his practice.

—Prince Ferdinand, of Bavaria, who is a distinguished surgeon, has, during his recent visit to Madrid, performed several delicate operations. The prince is a brother of the Empress of Austria-Hungary.

Items.

—If Queen Victoria does not celebrate her jubilee by a liberal assistance to the London hospitals, it will not be for lack of sufficient reminders from the medical press of England.

—The most effective, as well as most convenient cure for warts is said to be fifteen grains of corrosive sublimate dissolved in an ounce of collodion, the warts to be brushed carefully with the mixture once daily.

—Wilson Barrett upon being asked the other day how old he was, said: "When I play 'Chatterton' I am 17; when I play 'Hamlet' I am 20. That is all I am going to tell anybody about my age."

—Dr. A. J. Smith has been elected first assistant in the insane department of the Philadelphia Hospital, to succeed Dr. J. C. DaCosta, who has been called to a similar position in the Pennsylvania Hospital for the Insane.

—The Alumni Association of the Medical Department of the University of New York

held its sixteenth annual dinner at Delmonico's on the evening of January 27, when Dr. F. R. S. Drake presided, and the annual toasts were responded to.

—The report of the Pennsylvania Society to Protect Children from Cruelty for the year 1886 has just been issued in pamphlet form.

—The Emperor of China, says a correspondent of *Les Debats* insists on having bears' paws, antelopes' tails, ducks' tongues, torpedo-eels' eggs, camel's hump, monkeys' lips, carps' tails, and marrow bones served on his table every day in the year.

—The total number of students in the medical faculties of the German universities is about 300 in excess of what it was last winter session, the largest increase (seventy-six) being at Würzburg. Berlin shows a decrease of eight, and Königsberg a decrease of four.

—"See here, now, I've heard a good deal about the honest farmer, but what makes you put all the best apples on the top of the basket?" asked a city man of the fruit-seller. He thought a moment, and replied: "I s'pect it's for the same reason you have the front of your house of brownstone."

—Dr. John Van Voorst, who died in Jersey City Feb. 4, was a well-known practitioner. He was a graduate of Princeton and Bellevue Medical College. He was house physician at Bellevue Hospital, and also at Mrs. Astor's Women's Hospital for several years, and was on the staff of physicians at St. Francis' and Christ's Hospitals, Jersey City.

—The late Dr. Dudley, of Brooklyn, left a bequest of $500 to the Faculty of the Long Island College Hospital, to be used in encouraging their students to diligence in special study. The interest of this sum will each year be given to the senior year student who shall present the best thesis based upon some case that has been clinically observed during the year.

OBITUARY NOTICE.

George O. Moody, M. D.

At 11 p. m., Sunday, February 6, Dr. George O. Moody, of Titusville, Pa., while in the act of preparing for bed, fell dead almost instantaneously. Angina pectoris was the presumable cause, as he had suffered somewhat from that affection in the past. Dr. Moody was a member of the National and State Medical Societies, and had been appointed a member of the Council on Diseases of Children in the International Medical Congress, which was to meet in September. His loss will be widely felt.

Dr. George O. Moody held a first rank as a practitioner of medicine and surgery, and the community in which he labored so faithfully for 24 years will not easily replace him. Crawford County Medical Society, as well as the State and National organizations, will miss him and mourn his loss. His papers were scholarly and adorned the literature of our Transactions. His discussions were clear, intelligent, and practical, and his manliness and candor were as manifest in his profession as in all his relations and dealings with the public.

At a meeting of the members of the medical profession of Titusville held in Dr. Barr's office on the 7th inst., the following preamble and resolutions were adopted:

Whereas, We are called upon to mourn the sudden loss of our esteemed friend and fellow-practitioner, Dr. George O. Moody;

Resolved, That by the death of Dr. Moody the community has been deprived of an active, public-spirited citizen, his patients of a skilful, energetic, and sympathetic physician, his friends of a warm-hearted, earnest, congenial companion, and the profession of a bold, fearless, and honest practitioner, kind and courteous to his medical brethren, and one possessed of unusual acumen and skill, with a breadth of culture obtained by few.

Resolved, That we extend to his afflicted family our sympathy in their bereavement, feeling as we do that the loss is one personal alike to them and to each of us, as well as to every member of the community.

Resolved, That we attend his funeral in a body.

Resolved, That a copy of these resolutions be furnished to his family, and that we request their publication in the local papers and in the medical journals of our country.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1 54-1886

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease producing matter. INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

NEURASTHENIA.*

BY A. B. ARNOLD, M. D.,
Of Baltimore,

Professor of Clinical Medicine and Diseases of the Nervous System in the College of Physicians and Surgeons of Baltimore, etc.

The term "neurasthenia" was first introduced by the late Dr. G. Beard, of New York, to denote a peculiar functional disease of the nervous system. One of the principal reasons he assigns for the neglect of this nervous disorder by previous observers is the great difficulty of analysis and classification of its symptoms. Neurasthenia, he maintains, is exceedingly common in the United States, owing to the widespread influences that favor its development. Perhaps the frequency of its occurrence in this country is only apparent, for, as he remarks, Americans seek medical aid for the relief of ailments which, as a general rule, cause less anxiety to European people. Dr. Beard's first publication on this subject encountered much adverse criticism at home. Nervousness, or rather nervous weakness, it was said, had always been recognized as a morbid condition giving rise to a host of symptoms, clinically distinguished by designations in accordance with their supposed dependence on special disturbing causes. Every one is familiar with the phases such as cerebral anæmia, spinal irritation, the neuropathic diathesis, irritable weakness, oxaluria, etc., etc. Bouchut's nervosism not only included all the affections implied in the said designations, but embraced every possible functional disease of the nervous system. The Griffith brothers had before him indulged in an analogous exaggeration of the pathological importance of the so-called spinal irritation. Dr. Beard has fallen into a similar error, in claiming for neurasthenia a multiplicity and variety of symptoms which would hardly justify the attempt to set up any other species of functional nervous disease. But the merit cannot be denied to him that he opened a new line of investigation fertile of practical results. Every busy practitioner will admit that he frequently meets with obscure and anomalous symptoms which he finds difficult to refer to any individual disease with which he is conversant. If the patient be a female and the morbid phenomena point to disturbance of sensory or motor functions independent of any tangible affection, he is very likely to suspect hysteria. Supposing the patient is of the male sex, he will probably be tempted to seek for the cause in some disorder of the nervous system. It is curious to notice in this connection the colloquial change the word nervous has undergone. Originally it implied a vigorous quality, and we still speak of the nervous style of a writer. We now signalize a person as nervous when he is easily agitated or morbidly impressible. Experience did not fail to teach what physiology leads to expect, that numerous and diversified disorders of the nervous system are traceable to the debilitating influences of physical over-exertion and mental strain. The word nervousness is at any rate an unscientific expression. Dr. Beard deserves, therefore, much credit for having drawn attention to the great prevalence of nervous exhaustion and the many disguises it may assume.

*Read before the Baltimore Academy of Medicine, January 18, 1887.

Neurasthenia belongs to a group of neurotic diseases, having in common with all of them transmissibility and a tendency to appear under different forms, not only in different individuals, but in the members of the same family.

A recent German writer* indulges in some curious speculations concerning the important role which neurasthenia has played in shaping the destinies of races and nations. He says, "when historians speak of the degeneracy and effeminacy of celebrated people of the past, they only express in other terms the physical and mental deterioration of these people. That the nervous system received the chief brunt of the injurious influences which brought about such a change, may be inferred from its physiology. Thus the decadence of the Roman power dated from the introduction of luxurious habits and profligate manners. These causes undoubtedly tend to undermine the vigor of physical and mental health. Dr. Beard in the same strain warns his countrymen to take care of the nervous system. But be this as it may, when we come nearer our own time we see many influences at work bearing heavily on the integrity of the nervous apparatus. There is the mental strain which the hot race for wealth and distinction imposes; the unremitting toil to secure a competency; the anxiety and worry of those engaged in public life; the painful efforts to keep up appearances; the vicissitudes of fortune; the heart-burnings, the disappointments, and the numerous penalties we pay for our high-pressure civilization.

If neurasthenia, as Dr. Beard will have it, has picked out our country for its special visitations, it can only be that the etiological factors of this malady are more intensified among us than any where else. He refers to Russia, where, in contrast with the United States, France, England, and Germany, the occurrence of neurasthenia is generally believed to be almost unknown. The Russian novelist Tourgieneff does not share in this opinion. Many of his life-pictures of the different strata of Russian society give evidences of physical deterioration and premature mental decay.

As neurasthenia sometimes rapidly develops it must be assumed that such an occurrence depends on an exciting cause that suddenly overwhelms the nervous system. In general, however, the disorder comes on slowly, and is probably the final result of a combination of causes, that act as a drain upon the nerve force. This characterization of the pathology of neurasthenia serves to explain the absence of a destructive lesion, the multiplicity and purely subjective nature of its symptoms. Taking for granted that nervous exhaustion is the essential condition underlying the clinical manifestations of neurasthenia, it must necessarily happen that the energy of all the bodily functions subject to nervous influence will be lowered. Such a state of the general system labors under the disadvantage of losing its normal steadiness in the exercise of its various powers, and in consequence that morbid excitability becomes established, which goes by the name of irritable weakness.

An enfeebled nervous apparatus is also incapable of offering adequate resistance to morbific causes that would otherwise exert but little influence, hence the numerous ill-defined ailments of which neurasthenic patients constantly complain. Moreover, as the neurasthenic diathesis occurs in every conceivable grade of intensity, it is easy to understand why many of its symptoms are not considered outside the limits of health. Finally, it must not be forgotten that the insufficient control exercised by the higher nerve-centres leads to perversions and aberrations that constitute the most singular phenomena of neurasthenia.

It is usual to make the division of cerebral and spinal neurasthenia. As observed in actual practice, the symptoms of both forms of the disorder are frequently blended.

Among the cerebral symptoms of neurasthenia none is more conspicuous and constant than headache. Many instances of so-called sick headache are of a neurasthenic origin. Of greater significance is a peculiar distressing sensation of the head, which patients compare to the feeling experienced when some heavy body is pressed on the vertex. A young artist consulted me some time ago for the relief of just such a symptom, which he described to resemble the sensation as if his head were held in a vise. He had abandoned his profession on account of this complaint, which although it did not amount to actual pain, was nevertheless of an unbearable nature.* The scalp in neurasthenia is exceedingly sensitive to the touch so that the use of the comb and brush cause pain. Disorders of the special senses are very common, consisting of flickering before the eyes,

*Die Neurastherie, by Prof. Rudolph Arndt.

*Dr. F. Runge published in the *Archiv. für Psychiatrie* (vi. B.) a series of cases under the caption of "Kapidruck" (head pressure), which presents in many particulars the clinical features of neurasthenia. In nearly half of the cases the etiology embraced conditions and circumstances which are known to induce nervous exhaustion.

muscæ volutantes, asthenopia, noises in the ears, a perverted smell, and a sour pasty taste in the mouth. Sleep is much disturbed by terrifying dreams. Many patients declare they pass vigilant nights for weeks.

The psychical symptoms of neurasthenia usually partake of a depressing character. Sometimes they amount to utter despondency or melancholia. More frequently the mental irritability shows itself in curt answers, in exhibitions of a morose and peevish temper, and not seldom in a disagreeable selfishness. Probably the desire of subduing or chasing away the moods and vapors of which the patients themselves are conscious, is one of the causes that frequently lead them to resort to alcoholic stimulants and narcotics. When such patients fall into the habit of reflecting much on their unpleasant feelings, they are sure to become confirmed hypochondriacs.

Morbid fears constitute another set of symptoms which occasionally plague the neurasthenic. Agrophobia, or the fear of open places, is most frequently observed; claustrophobia, or the fear of narrow places; anthrophobia, or the fear of meeting crowds of people; mysophobia, or the fear of contamination, come less frequently under notice. A variety of these morbid fears I have observed in one of my patients, which I have not yet seen mentioned. A middle-aged gentleman who had been unfortunate in stock speculations and had suffered for many years from bleeding piles, kept himself in a constant state of misery from self reproach because he blamed the death of one of his friends to catching cold, which might have been prevented if he had not kept his friend standing for a considerable time in a cold draught of air during an interview. When my neurasthenic patient takes a walk he constantly looks out for some substances on the pavement that may possibly cause people to slip and fall. Should he find the end of a nail sticking out in the buildings he passes, he immediately sets about to knock it in. He stops to adjust a loose brick in the sidewalk, and he has been known to give notice to owners of lumber yards to remove a piece of timber that happens to project from the pile. A very strange neurasthenic symptom among patients of education and culture is the brooding over the insolvable problems of the universe or some puzzling metaphysical question. Such unbidden thoughts incessantly harrass them, however much they may try to banish them from their minds. But the saddest of all the psychical manifestations of the disorder is the tendency to drift into some debasing vice. The low appetites and propensities appear to gain the mastery over the diminished resistance of the moral power.

An enormous array of symptoms is attributed to the spinal form of anæsthesia. This is due to the extent and variety of functional disturbances resulting from an unstable and irritable condition of the spinal nerve centres. There are few neurasthenic patients who do not suffer from eccentric neuralgic pains and muscular weakness of the lower extremities. Real paralysis does not occur, but there is a constant feeling of fatigue and a desire for rest. Patients feel weary and exhausted after ordinary exertions. Lumbar or sacral pain seems to be never absent. The general sensibility is heightened. Slight pressure of superficial nerves causes tingling; the contact of cold substances produces pain. There is a sensation of burning in the palms of the hands and soles of the feet. Neurasthenic females complain that their shoes press too tightly, and their dresses make them feel uncomfortable, all of which is provoking to tradespeople, who despair to please such customers. The reflex excitability is augmented. Micturition and defecation may, in consequence, be attended with much discomfort. Muscular hyperæsthesia causes twitching of muscles and painful movement of the joints. Paræsthetic symptoms are felt everywhere, consisting of numbness and the sensations of pricking and formication. Vaso-motor disturbances bring on fitful flushings of the face and partial sweatings. I remember the case of a young shop-girl who had broken down in health and became the victim of a large number of neurasthenic symptoms. She had frequent attacks of palpitation of the heart and constricting pain about the chest. These attacks were ushered in by extreme reddening of the right ear and neighboring part of the cheek. The same side of the face broke out afterwards into a profuse perspiration. The respiratory symptoms are sometimes of an alarming character, consisting of embarrassed breathing and a choking sensation attended by a tumultuous action of the heart. The gastric disturbance witnessed in neurasthenia constitutes the so-called "nervous dyspepsia,' which is common in over-worked clerks and seamstresses, and no less also among people in different walks of life that impose varied hardships and the deprivation of the required rest and sleep. Such a dyspepsia baffles the usual remedies, unless a change of habits and pursuits be adopted.

It is hardly necessary to mention that the

diagnosis of neurasthenia should not be lightly made. Chronic and progressive diseases in their early stages often give no other intimation of their existence than the evidences of a declining state of the general health. The nervous depression, which is then surely to ensue, is liable to lend a neurotic feature to the ill-defined symptoms depending on the undeveloped disease, and the more so, if the patient is constitutionally predisposed to nervous affections. On the other side there is a risk to mistake neurasthenic symptoms for serious organic trouble. The experienced physician will find no great difficulty to distinguish neurasthenia from allied nervous disorders, though it must be confessed that the pictures presented by this class of maladies are so frequently confusing by their variegated coloring, or so frequently change into dissolving views, that their distinction often turns upon the choice of a phrase.

There is great scope for the display of tact and judgment in the treatment of neurasthenia. The number and complexity of its symptoms, their fluctuation and proneness to relapses after encouraging improvement, heavily tax the therapeutical resources of the attending physician. He would do well to take the patient into his confidence should there exist the least reason to believe that preventable etiological factors are at work, which on being abandoned or removed will materially assist the treatment. The patient may either require absolute rest and quiet, or be benefited by exercise that does not fatigue. The recuperative influence of mountain air or a visit to the seashore may, under circumstances, be indispensable. Dr. Beard says he has seldom found general anæmia associated with neurasthenia. My experience induces me to differ from him. A judicious course of tonic remedies is often of great value in long-standing cases. For the restoration of the muscular vigor, as Dr. Beard has indicated, nothing can surpass the refreshing effects of general faradization. After a number of trials with various remedies which stand in repute for the relief of nervous headache, I give now the preference in the neurasthenic variety to a combination of ether and the tincture of cannabis indica, in doses of twenty drops of the former and ten of the latter. Sometimes these remedies act better after a good night's rest has been obtained from a full dose of chloral hydrate. Great caution is necessary in the administration of opium or any of its alkaloids, for fear of inducing a disastrous habit, to which neurasthenic patients are particularly inclined. The practice of giving now large and repeated doses of the bromides is open to much less objection. In regard to arsenic, phosphorus, and the salts of copper and zinc, which are empirically ordered in neurotic affections, I cannot say anything of a positive character concerning their employment in the treatment of neurasthenia.

ON ABDOMINAL SECTION FOR TRAUMATISM.

BY THOMAS S. K. MORTON, M. D.,
Of Philadelphia.

The term "abdominal section for traumatism" is meant to include those cases where the operator deliberately opens the belly, or greatly enlarges an existent wound, for the purpose of discovering intraperitoneal wounds, and, if they are present, repairing them as far as possible, together with more or less final cleansing of the peritoneal cavity. Such cases as those in which wounds of prolapsed viscera are simply repaired, and the parts returned to the abdominal cavity, are not included. My excuse for this paper is, that I have been so fortunate as to be associated as an assistant to more than one-half of all the cases that have occurred in Philadelphia. In four of the cases I have been the assistant, and in three the care-taker also. These four cases have been treated in the Pennsylvania Hospital.

The indications for abdominal section for traumatism are in many cases very clear; in others, with only our present knowledge, exceedingly obscure. Taking up the consideration first of wounds, it seems to me that, with what we already know, the operation is clearly indicated in every case where penetration of the abdominal cavity is proven, and with fair surroundings it becomes one's duty to open the abdomen and search for wounds, for there are no omnipresent symptoms which invariably indicate intraperitoneal wounds, even when extensive. With reference to the cases suitable for operation, I would say that, besides gunshot wounds, stabs, etc., which have already been operated upon, I conceive that in the future many other traumatic conditions will be subject to interference by section, such as rupture of the stomach, gall-bladder, spleen, or kidney, ruptured blood-vessels, various hæmatoceles, etc. Dennis, of New York, had a case in which he opened a penetrating stab wound of the abdomen. He found, besides the injuries, an intussusception evidently caused by the violent peristalsis excited by the point of the knife touching the intestine, and I there-

fore conceive the possibility of intussusception without wounds. In this paper, no consideration is paid to the effects of traumatism upon diseased organs, such as ulcerated stomach or bowels, or upon the pregnant uterus or its diseased appendages, or perforating typhoid ulcers.

I shall consider the subject of diagnosis as a whole, with the exception of that of ruptured bladder, which I shall take up later. The diagnosis of penetrating wounds of the abdomen is occasionally very easy—occasionally exceedingly difficult. Where there is a pistol-shot wound of the anterior wall of the abdomen and a probe can be inserted, or where there is extravasation of feces, the diagnosis is easy enough. Emphysema is given as one of the best symptoms of perforation of the intestine. I regard it as a poor one. One of the cases occurring in the Pennsylvania Hospital presented marked emphysema of the abdominal walls without injury to the lung or intestine. Injury of the lung may give rise to emphysema, which may be mistaken for that due to a wound of the intestine. Diminution of the liver dullness due to the escape of flatus into the abdominal cavity is another symptom, but this is fallacious. Shock is usually marked, but in some cases the patient is not at all shocked. Instances are on record where patients have walked long distances, and yet, on opening the abdomen, wounds of the intestines have been found. One man did not even know that he was shot until he had walked some distance to his home—yet he had numerous intestinal perforations. Of course, vomiting of blood and the passage of bloody stools are good signs, but they are not always reliable. The symptomatology of penetrating wounds of the abdomen is very obscure, and we should like to have some light thrown upon it. Of course, a wound through the back is more difficult to diagnose than one from the front, and frequently the diagnosis can only be made by incision. Even where the ball is found lying under the skin, you cannot be sure, for it may have passed around the abdomen. The most interesting class of cases is that in which there has been a blow or injury upon the abdomen, and we suspect rupture of the intestine, the spleen, liver, or blood vessels. These are most difficult cases to diagnosticate, and I predict that in the future we shall open many abdomens in order to determine whether or not these conditions are present.

In regard to the surroundings under which one should operate. In a metropolitan hospital, surrounded by every convenience, I think that the majority of cases should be operated upon. In cases where injury to the gut is known to have occurred, and in many cases where it is suspected, it is our duty to operate. In the country, and in unskilled hands, only those cases which are the most desperate should be operated upon, unless they can be removed to some centre.

If the patient appears to be coming out of shock, he should be allowed to do so as far as possible. Shock from hemorrhage is, of course, the worst. Where there is extravasation, the shock will be kept up, and under such circumstaces etherization and removal of the cause would be the best way to overcome it. The preparation of the patient should be by judicious treatment and thorough cleansing. I shall not to-night go into the subject of antisepsis or asepsis, although I hold positive views of their great value. Everything should, however, be surgically clean.

Where there is a wound of the anterior wall of the abdomen, first prove perforation by cutting down to the peritoneum. That should be a sufficient warrant for section. In wounds of the back some judgment must be exercised. The incision should, I think, in almost every case be median. In the majority of the cases recorded, and, I think, in nearly all the successful cases, the incision was median. In several instances where section has been done for a special purpose, such as removing an injured spleen, the incision has been made to one side of the median line. In one case of stab wound which I saw, the original wound was enlarged and gave rise to great difficulty in the subsequent steps of the operation. One wound was overlooked in that case, which error, I think, was largely due to the position of the incision. The length of the abdominal wound is to be governed by the circumstances of the case. It may extend from below the ensiform cartilage to the pubes. There is no harm in a long wound if it be properly treated. After opening the peritoneum, note carefully the abdominal contents. If we find fæces we are encouraged to prolong the search until the wound is found. If there is blood, we should look for the vessel injured. The search for wounds should be thorough and systematic. In most of the cases where wounds have been overlooked, it has resulted from not making a systematic examination. We should begin at the entrance of the œsophagus into the stomach, if it is possible to reach that high, go over the stomach and all the intestines, examine the mesentery, the rectum, and

bladder, and look at the spleen. Unless this is done, wounds will sometimes be overlooked, and even apparently with apparently the utmost precaution they will sometimes escape detection. Only those who have seen such cases can imagine the difficulty experienced in finding some wounds, especially when the upper part of the transverse colon and the surrounding omentum are involved. If the intestines are much distended, it may be necessary to puncture them. It is important to remember that extravasation has followed such a puncture, and they should always be closed with a Lembert suture. If the vermiform appendix or an epiploic appendage is injured, it should be excised. In wounds of the intestine, it makes a difference whether the injury is the result of a gunshot or of a stab. Gunshot wounds are more apt to slough than knife wounds, and where many wounds of the former are located close together, it has been found advisable to excise a portion of the gut, including the numerous wounds. Probably a foot of the bowel may be excised without much disadvantage. Six or eight feet have been excised, but in this case the operation was followed by emaciation and death. In such a case it would probably be better to make several excisions. Perforations when found should be turned into the bowel by the suture of Lembert. Wounds of the large intestine and stomach are to be treated in the same way.

Where the ball has perforated the mesentery, the wound edges should be excised. This is the opinion of those who have done most operations. The opening is then brought together with stitches on both sides, or passing all the way through. If the omentum be badly injured, no harm will come from its excision. It may be ligated in various places and the whole cut off without injury. In a hernia case, I cut off what I supposed to be almost the whole omentum, and the man got perfectly well. Where the spleen is wounded, the only method seems to be to excise the organ. This has only been done, so far as I know, twice. Very little is known about the treatment of injuries of the spleen. Wounds of the liver have been met with a number of times, and all the cases have died. Whether or not it would be practicable in these cases to stitch the liver to the abdominal wall, etc., I cannot say. Tait has done it in chronic disorders a number of times, and has had favorable results. We should be encouraged to experiment in this direction. About wounds of the pancreas little is known—I doubt if they could well be reached. If the kidney is extensively wounded, its excision or complete drainage is indicated. If the ureter is divided, the only remedy is excision of the corresponding kidney. If the projectile has gone through the diaphragm, the same operation as in the case of the mesentery would be indicated, namely, excision of the edges and sutures. Of course, all bleeding vessels are to be tied. If this is impossible, the main trunk, even if this be the aorta, must be tied. Wounds of the uterus and appendages have not been dealt with, but would probably require excision.

Then there is another class of wounds entering the abdomen—that is, wounds through the vagina and rectum; for instance, a stab wound through the vagina. If we knew that it penetrated, abdominal section would be indicated. In all these cases contusions or brush burns of the omentum and intestine frequently are found. In time, nearly all of these will slough and give rise to pus. In several cases death has been attributed to this cause. All severe contusions involving the mesentery or omentum should be excised. When they involve the intestine, the peritoneum should be united over them with Lembert sutures. The suture materials which I have seen used have been silk and catgut. I think the latter is preferable, if fine and chromicized.

One of the most important things that we can consider, is the time after injury when the operation should be performed. The sooner the operation is performed, the better are the chances of the patient. The cases in which the time is reported number forty-five. The average time after the injury for which operation was done, was eighteen and a half hours. Deducting four cases where more than two days had elapsed, the average falls to twelve and a half hours, while a deduction of all the cases where the time was over twenty-four hours, brings the figures to nine and a half hours. The average time after the injury when the operation was begun in the successful cases was seven and three-quarters hours; the average in the fatal cases was twenty-three and one-quarter hours. These are significant facts. In the five cases operated on at the Pennsylvania Hospital, the average time was six hours. Deducting one case in which from unavoidable circumstances twenty hours elapsed, the average comes down to three hours.

In all cases the question of drainage will arise. It is always difficult to decide, in any given case, whether drainage should be employed or not. If there have been extravasation and numerous wounds, drainage seems

to be indicated. Glass and rubber tubes have been used with apparently equal success and failure. I think that tubes of glass or other hard material are to be preferred. Where there has been extravasation of the contents of the stomach or intestine, this is usually followed by great oozing of serum.

The final steps of the operation are irrigation and cleansing. In irrigation I believe most thoroughly. It should be very large in quantity, and can hardly be too much so. If the patient is shocked, there is no better treatment than pouring hot water through the abdominal cavity. It probably acts directly upon the solar plexus. I have seen this frequently used with marked benefit. The patient will be in far better condition after the use of a gallon or more of water at a temperature of 100° to 110° than before its application. It has occurred to me that in profound shock from other causes, it might be well to puncture the abdomen with some form of double canula and thus irrigate the abdominal cavity with large quantities of hot water. What shall be put in the solution used for irrigation? Several agents have been so used: Water, distilled water, boracic acid solution, mild solution of bichloride of mercury, and solution of carbolic acid. Carbolic acid should be expunged from the list. Bichloride of mercury, when employed, should be in very dilute solution—1 to 5,000 or 10,000. Boracic acid was used in two successful cases in three per cent. solution in unlimited quantities. In four cases at the Pennsylvania Hospital the bichloride solution in the strength of 1 to 5,000 and 1 to 10,000 was used and apparently without any bad effect. It was used in both of the successful cases there. Distilled water is very good and especially in cases where extravasation has not occurred. Where there has been extravasation, purulent peritonitis set up, or it is not certain that all foreign matters have been removed, I think that an antiseptic is indicated. Where we have a solution like that of boracic acid, possessing fair strength with little danger of poisoning, it should be used. The parietal wound is closed and dressed in the usual manner.

One question in the after-treatment would arise in cases where a drainage-tube had not been left, and would be with reference to reopening the wound and draining where a large amount of serum was present. Each individual case must be decided for itself. The onset of violent peritonitis would be an indication for reopening the belly, irrigating and draining it.

Now a few details with reference to ruptured bladder. The symptoms of ruptured bladder are more definite than those of most other cases. The condition of the bladder at the time when the injury is received is of some importance, but cannot always be ascertained. Shock is usually present, as in other cases. Pain in the hypogastrium, fruitless efforts at micturition, vomiting, hiccough, distension of the abdomen with fluid, the withdrawal of blood or bloody urine by the catheter, are all good indications. If there is no urine in the bladder, or none comes in, it is a fair sign. The catheter can sometimes be introduced to a great length, and occasionally the rent in the bladder wall may by this means be detected. The withdrawal of an enormous quantity of fluid is another indication. If warm water is injected, it may be felt by the patient in the loins and other locations. With the catheter in the bladder, the liquid sometimes ebbs up and down with the movements of respiration. Recently Dr. Weir, of New York, has suggested a test for ruptured bladder, which consists in injecting a certain amount of fluid and percussing over the region of the bladder. If a definite outline of percussion dullness is noted, it is a fair inference that the bladder is not ruptured.

It is important to determine whether the rupture is extra or intra-peritoneal. Stephen Smith has shown, in a collection of 65 cases, that the peritoneum is injured in 80 per cent. of the cases. Max Bartles found, in an examination of 166 cases, that the rent was intraperitoneal in 98, and extraperitoneal in 54. In 84 cases of intraperitoneal rupture the rent was situated at the fundus in 40 cases; in front, near the fundus, in 9; posteriorly in 33; and at the side in 2 cases. In 50 cases of extraperitoneal rupture, the rent was at the neck in 19, anterior in 23, posterior in 2, and at the side in 6. In 15 of these cases there was fracture of the pelvis. In these cases, as a rule, the urine found in the peritoneum is healthy, and not decomposing. An interesting paper has been published by a Russian, giving the toxic effects of urine which has escaped into the peritoneal cavity.

The method of operating is an interesting one. Having determined upon interference by section, whether the diagnosis has been made positive or not, a median incision should be made and enlarged to suit the convenience of the operator. The incision may at first be made down to the bladder,

as for a suprapubic lithotomy. If there is a wound in front, you may feel if it enters the peritoneal cavity; but even this is fallacious. Having found the wound in the bladder, the first thing is to clean the peritoneal cavity. Next, it is necessary to get the bladder into a position to suture it. This has been, until recently, found one of the most difficult steps of the operation. To obviate this, distention of the rectum with a colpeurynter has been practised. More recently, as in the case of Fox, sutures have been introduced on either side, and may be combined with the use of the colpeurynter. MacCormac, who found considerable difficulty in bringing up the bladder, made a lateral incision on each side through the peritoneum. This liberated the bladder immensely. These peritoneal wounds he stitched together in the usual way, but it appears to me that this might be improved upon by introducing the stitches as Dr. Emmet does when sewing up his relaxation incisions of the vagina or elsewhere—that is, by uniting the wound by stitches passed in its longitudinal diameter. It has been found that the cases in which the sutures penetrate all the coats of the bladder invariably terminate fatally. This must be borne in mind, and the sutures passed through only the serous and muscular coats. The bladder wound is to be brought together with Lembert sutures of silk or catgut.

The after-treatment brings up the question of drainage, which has been discussed. A catheter should be left in the bladder. Another important thing is to prove that the stitches effectually control the opening in bladder. This is done by injecting some solution—better, a weak antiseptic solution—into the bladder. If there is any leakage, additional sutures should be introduced; or the first row of stitches, by a second set, turned in.

THE BONE-SCREW.

BY J. S. WIGHT, M. D.

Professor of Operative and Clinical Surgery at the Long Island College Hospital.

In exsection of the knee, I have found that the wire suture held the bones imperfectly in place, and was not readily removed subsequently. In cases of resection of the ends of bony fragments after non-union, and where there has been marked deformity, I have also found the wire suture frequently incompetent to prevent lateral displacement. As a substitute for the wire suture I have used nails and screws, which have done excellent work. I have used the wire-nail, which is about three inches in length and a little over one-eighth of an inch in diameter. It has a flat head on one end and is pointed at the other. The way I use it is as follows: After resection of the knee-joint, a hole is drilled through the tibia from before backward and upward, so as to emerge near the middle of the surface of the upper end of this bone. The nail is gently driven into this hole and made to emerge at the proper point in the cut surface of the lower end of the femur, into which it is driven about an inch. Then neither bone can become displaced laterally in any direction by any reasonable force that may be applied. Of course the limb must be placed on an appropriate splint till repair can take place. When the bones have united, the nail is simply pulled out. I have used the lion-forceps, as well as my fingers, for this purpose. A *round* nail like this is superior to a quadrangular one, and is far better than any form of wire-suture. I have also had long, slender steel screws constructed by Tieman & Co. to take the place of the wire nail. These screws are from three to four inches in length and about one-eighth of an inch in width. The way they are put in is to drill a hole with the surgeon's drill and then screw them into the bone. Tieman & Co. have made me a special instrument for this purpose, which will not only drive the screw in, but will take it out when it has served its object. The screw is less apt to injure the bone than the nail. The last case in which I used the bone-screw was in a case of vicious union of the fragments in a fracture of the right leg. After resection, I drilled a hole through the lower end of the upper fragment, obliquely downward and backward, into which I turned the bone-screw, and then I brought the bony fragments into proper relation, and drove the bone-screw, by means of its handle, into the upper end of the lower fragment, which was firmly held from any lateral displacement. The handle was then detached and the upper and square end of the bone-screw was left projecting, so as to be ready for removal after union of the fragments. There was not the usual mobility I have had after wiring the fragments of bone. In fact, the condition was extremely satisfactory. And when I dressed the limb subsequently, the fragments kept their places in the most perfect manner. The use of the bone-screw in keeping the bones in relation after exsection of the knee-joint was also very satisfactory. And when the union is firm enough the bone-screw is removed.

Hospital Reports.

ST. MARY'S GENERAL HOSPITAL, BROOKLYN.

Service of Benj. F. Westbrook, M. D.

Reported by Dr. Glentworth R. Butler, Associate Physician to Throat and Chest Department.

Angeiospastic Angina Pectoris.

J. D., male, aged 40, farm laborer, admitted November 25, 1886. This patient states that seven years ago he was suddenly seized with very severe pain on the left side, extending from the shoulder to the foot. The attack lasted several hours, and was followed by another on the following day. Three and one-half years later this experience was repeated. He was perfectly well in the interval, and since the last attack has been in apparent good health until to-day, when he was brought in by the ambulance suffering from a renewal of his old symptoms.

The patient was slightly anæmic, but fairly well nourished. A careful physical exploration revealed no apparent abnormality, either thoracic or abdominal. There was a point of tenderness over the lower end of the spine.

A paroxysm, or more properly a series of paroxysms witnessed by the writer, presented some points of interest. The patient stated that the pain began in the præcordial region, radiated into the neck, down the left arm, and into the left leg as far as the foot. In the extremities it was accompanied with numbness and formication. A fear of impending death was present. After the attack was fully inaugurated the patient lay upon the left side with the knees drawn up, and the hands pressed firmly upon the lower end of the sternum. The face wore an expression of agony. The surface was pale, but the veins being somewhat distended gave it a purplish hue. The breathing was slow and labored, not the labor of dyspnœa, but as if after expiration the breath was held as long as possible from fear of movement. The pulse was very rapid, 160 per minute, and a mere thread under the finger. In the height of the seizure it was extinguished. Auscultation showed a weak and rapid heart action, and a faint but perceptible systolic murmur at the apex. As the pain decreased in severity the pulse became slow and full, and the bruit disappeared. A paroxysm lasted about five minutes, and unless controlled by remedial agencies another would soon commence, the pulse becoming progressively smaller and more rapid as the pain increased.

For the relief of the paroxysms, spirits chloroformi by the mouth, and amyl nitrite by inhalation were first used. The latter, although pushed to its physiological limits, had very little effect. This was also true with regard to chloroform by the mouth. Morphia was effective to limited degree. Large doses of spirits etheris and whisky were apparently beneficial, facilitating the eructation of quantities of gas, which attended the close of a series of attacks. The most effectual resource, however, was chloroform by inhalation, pushed to surgical anæsthesia. It was considered safe to use it in the absence of any signs of notable organic disease or weakness of the heart. Under its influence the pulse changed in a few minutes from a rapidly vibrating thread to a full, slow beat, and the cardiac sounds underwent a corresponding alteration. The constitutional treatment consisted at first of iron and quinine to remedy the existing slight anæmia. Fowler's solution was then given, and slowly increased to toleration. Since he was put upon arsenic the intervals between the paroxysms have materially increased, averaging twelve days instead of six.

There are some points of interest connected with the case. It appears to be a good example of vaso-motor angina, as evidenced by the progressive contraction of the radial, and its relaxation under chloroform. Amyl nitrite failed to loosen the vaso-motor grip. The occurrence of mitral systolic murmur during the paroxysm has not been noted, so far as the writer is aware. It is explained by the existence of a vaso-motor obstruction damming the blood back upon and distending the left ventricle, thereby causing temporary functional incompetence of the mitral valve.

As to the ultimate cause of the attacks in this particular case no opinion can be expressed. The prognosis is fairly favorable in the absence of definite signs of organic disease.

Empyema—Perforation of Lung.

J. S. C., male, aged thirty-six, clerk, admitted December 14, 1886. In February, 1886, this patient had an attack of pleurisy from which he is said to have recovered. In April, 1886, a second attack occurred. Since then he has been short of breath, and had a cough with scanty whitish expectoration. One week ago cough increased, and the expectoration became abundant, grayish, and foul-smelling. The appetite is poor. He has lost flesh and strength. The bowels have been regular up to two days ago, when a profuse diarrhœa occurred. Has been

feverish, with occasional sweats. Has been a a drinking man for several years.

Physical Examination.—Over the right chest, anteriorly, the expiration was prolonged and low-pitched, with some fine moist râles at the apex. Over the left chest, anteriorly, there was slight dullness at the apex, increasing downward and passing into flatness below the third rib. Over the left chest posteriorly, there was dullness at the level of the scapular spine, passing into flatness at and below the angle of the scapula. Over the areas of flatness the vocal fremitus had disappeared, and faint and distant bronchial and amphoric breathing were heard. Ægophony was present over the left base below the angle of the scapula. A hypodermic syringe drew off some extremely fœtid pus. The evening temperature was 101° F. Pulse 126 and weak. He was put upon a liberal allowance of stimulants, with digitalis, quinine, and nux vomica.

On December 18, thoracotomy, with resection of a rib, was done by Dr. B. F. Westbrook after a preliminary aspiration to again verify the presence of pus. An incision three inches long was made over and parallel to the sixth rib in the left mid-axillary line, down to the periosteum. The latter was incised and raised from the rib for an inch in length and around the entire circumference of the rib. The corresponding portion of the rib was then exsected with bone forceps, leaving the pleural cavity unopened. The pleura, with the adherent layer of periosteum, was then incised, giving exit to a pint of excessively fœtid pus and gas. The pleural cavity was thoroughly irrigated with a $\frac{1}{6000}$ solution of hydrarg. biniodide, and a rubber drainage-tube inserted, passing in for about six inches toward the posterior portion of the base of the chest, as verified by careful exploration. The wound was closed around the tube by silk sutures, powdered with iodoform, and a paper-wool dressing applied. During the operation, the patient became cyanotic, but rallied under hypodermic injections of whisky. For nine days after the operation the patient's condition improved materially. The cough almost ceased, the temperature went down to normal, rising occasionally to 100.5° F. The pleural cavity was irrigated twice daily with 2.5 per cent. carbolic solution. The discharge lost its odor, became serous and diminished. The drainage-tube was shortened from day to day. But on December 27, he developed a colliquative diarrhœa. In spite of remedial agents, embracing peptonized milk, nitrate of silver, acetate of lead, various preparations of opium, bismuth, sulphate of iron, catechu, and other measures, the diarrhœa continued obstinate, hiccough set in, the pulse rose to 130, the adynamia increased, and the patient died on January 2, 1887. No autopsy.

In this case the pus had probably been in the pleural cavity for at least six or seven months, and perforation of the lung had existed for several weeks. During this time the fever and imperfect nutrition had been acting upon an organism reduced in resisting power by alcoholic excess. Consequently, the case was very unpromising when submitted to operation. The latter was successful in removing the source of the septic fever, and so far as the pleural cavity was concerned the prospect of recovery was good. But the enfeebled digestive and nervous systems were unequal to their work, and the patient succumbed. The two days' diarrhœa before entering the hospital was a premonitory sign of the final event.

The Treatment of Croupous Pneumonia.

R. B., male, aged 20, iceman, admitted October 14, 1886. This patient was a robust young German. Two days ago, after dancing until he perspired freely, he rode for some distance in a cold wind. Had a violent chill, followed by great prostration and shortness of breath and cough. These symptoms continued until his admission. A physical examination showed crepitant rales over both lower lobes, and right middle lobe. Over the right lower lobe the breathing approaches bronchial; face much flushed; nares acting; rusty expectoration. The evening temperature was 106° F., respiration 46, pulse 126. Mustard poultices were ordered to the chest. Milk diet. Ten grains of calomel were given, and a half drachm of antipyrine. The next morning, October 15, the temperature had fallen to 104°, respiration 42, pulse 118. Patient feeling comfortable. He received again ten grains of calomel with an equal quantity of powdered jalap. Antipyrine was ordered in ten-grain doses every two hours, whenever the temperature rose above 101° F. The bowels moved freely. By October 19th the evening temperature was 100.5° F., respiration 34, pulse 80. At this date no abnormal signs existed over the left lung, and the pneumonic sputa had almost ceased. Over the right base posteriorly, below the angle of the scapula, there was flatness on percussion, absence of breathing and vocal resonance. There was no dyspnœa, and patient felt well. Antipyrine and poultices discontinued. The right

side was painted with iodine, and on October 22d, when the morning and evening temperatures were normal, he was put upon half drachm doses of syrup of the iodide of iron. Under this treatment the fluid in the right pleural cavity rapidly diminished in quantity, and on November 3d, when he was discharged, there were no evidences of its existence.

In this hospital excellent results have been obtained with antipyrine and calomel in acute lobar pneumonia, especially in the sthenic varieties. The more sudden and intense the invasion, the more marked the results. It is difficult to believe that in this case, with an initial temperature of 106° F., the pneumonic process was not materially modified by the treatment. Although the local inflammatory lesion undoubtedly began in the pulmonary parenchyma, its intensity was sufficiently great to cause a pleurisy with exudation.

Medical Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated meeting January 26, 1887.

The President, J. Solis-Cohen, M. D., in the chair.

Discussion on Abdominal Section. (*See page* 260.)

Dr. Charles B. Nancrede said: "I understood Dr. Morton to say, that the case of suture of the intestines for ball-wound which he reported was the first so treated in Philadelphia. He is mistaken, for I operated on a case of gunshot wound of the abdomen some seven months ago, and reported it to the Academy of Surgery about three months ago. I should like to compliment the Doctor on the immense amount of labor evidenced by his paper. I think this is a timely subject for discussion. Some three months ago I had the privilege of taking part, by special invitation, in a discussion on gunshot wounds of the small intestine, which took place in New York; and was participated in by most of those who had operated up to that time. The conclusion arrived at was that all penetrating ball wounds of the abdominal cavity demand at least an exploratory operation, and if any wound of a viscus be found, its repair should be attempted. I should like to enter a protest against the evident tendency to advise the opening the abdominal cavity by any practitioner in every ball wound. Where a large tumor has been removed the abdominal walls are lax, and there is plenty of room for manipulation. In laparotomy for gunshot wounds or other injuries, the difficulties are ten-fold. You have to operate through a tight and narrow opening. In prolonged operations there is often difficulty from distention of the intestines. The difficulties in finding the wound are sometimes exceedingly great; so much so that if I had a ball wound in the abdominal cavity, unless I could be operated on by one who was in the habit of doing abdominal operations, I should rather trust to the old let-alone plan. I have seen undoubted penetrating ball wounds of the abdomen recover.

"Let me say a few words about my own case, which, I think, shows the important point, although I could not secure a post-mortem, that peritonitis is not the only thing we should dread. I saw the boy six hours after he had been shot. The wound was a little to the left and above the umbilicus. He vomited blood one hour and a half after admission, although the operation showed that both the anterior and posterior walls of the stomach had been perforated. I determined that the wound was a penetrating one and made an incision in the median line; and I would warn any against enlarging the existing wound, if not in the median line. I found a wound of the anterior wall of the stomach which I closed with fine silk, using a fine sewing needle. Then I found a wound in the anterior wall of the duodenum, which I sutured. I next looked for and found a wound of the posterior wall of the stomach. A large ragged wound in the posterior wall of the duodenum was also discovered. Examination from the stomach down almost to the ilio-cæcal valve revealed no other wound. A careful toilet of the peritoneum was made and the wound closed. The boy did well for forty-eight hours, and never presented the least symptom of peritonitis. When peritonitis comes on suddenly there may be a profound condition of shock which will not admit of rise of temperature, rigidity of the abdominal muscles, flexion of the limbs upon the pelvis, pain, or any of the usual symptoms, but this is not the case in slowly developing peritonitis. The boy died on the third day with a series of convulsions with very high temperature. I believe that he died of sapræmia, due to the absorption of ptomaines. The cold water coil, which was used almost from the outset in both of the successful cases of Bull, of New York, was not used, and I think more opium was given

than was wise. We have long been taught to give opium in full doses in traumatic peritonitis, but I believe that many cases are killed by this treatment. When the initial symptoms are marked by collapse, low temperature, rapid, feeble pulse, and clammy skin, if you give large doses of opium simply to ward off the expected inflammation, you will probably kill the patient. If you give moderate doses of morphia with large doses of atropia, you possibly rally the patient and carry him over the shock stage. I think that large doses of opium should not be given in peritonitis unless guarded by atropia. It should be given by hypodermic injection, for you do not know how much will be absorbed from the stomach. At the end of a peritonitis where, from the respiratory centres becoming involved and from interference with the action of the diaphragm by tympany, hypostatic congestion of the lungs is taking place, persistence in the use of large doses of opium will kill the patient. If the opium is reduced to a minimum and given with large doses of atropia, or atropia is alone exhibited, you will sometimes tide the patient over.

"I think we should enter a word of warning against the tendency to operate on every case of abdominal wound without proper precautions. It should be done by a skilled hand. Not every case is fitted for it. The condition of the patient should be carefully considered before such an operation is attempted, and I hope the Society will be careful how it endorses an operation of this kind as the *rule* for penetrating wounds, without further light upon the subject."

Dr. S. S. Cohen said: "Dr. Morton has spoken of the injection of hot water into the abdominal cavity for the purpose of restoring the pulse in cases of severe shock and collapse. It may be interesting to mention that Dr. Benjamin Ward Richardson records successes following injection of hot milk into the abdominal cavity for the purpose of restoring patients in the collapse of cholera. The same measure has been used successfully by others."

Dr. Morton also stated that he knew of no case in which poisoning with boric acid had occurred. Such a case has been reported in the *Medical News*, some two years ago, by Dr. Brose, of Indiana.

Dr. G. G. Davis said: "We have been taught that penetrating wounds of the peritoneum are not to be probed. The author has mentioned this as one of the means of diagnosis. If other diagnostic points are present, probing is not necessary; still, I think it justifiable to use the probe if it is done antiseptically. The time of probing was not touched upon. This, I think, is a very important point. When called to see a man who has been shot in the abdomen or any other part of the body, the question arises whether or not it is justifiable to probe the wound at once. I believe that it is not, unless certain precautions are taken, and unless the surgeon is prepared to follow up his examination, if necessary, by operation. If there is hemorrhage it requires attention. Outside of that I can conceive of no circumstance which will require immediate manipulation of the wound. The examination should be deferred until the patient is brought to the hospital or to his home and the examination made once for all, at the when the surgeon is prepared to go on with the operation, if one is necessary. The indiscriminate examination of Garfield's wound was severely criticised by Esmarch, and he had good grounds for his criticism. I have not seen many cases of gunshot wound, but I can recall three cases in which the abdomen was involved. In none of these was any operation performed, and they all speedily died. If the operation is to be done, it should be done early. The cases which I have seen remained in a comparatively good condition for a few hours, but toward the end of the first or second day many of them will die, particularly if the wound is a large one. They seem simply to sink away.

"As regards the use of hot water injected into the abdomen, a less radical method is the injection of the hot water into the rectum, which is frequently used and which I employed at least six years ago. A temperature of 108° to 110° will be found comfortable."

Dr. Morton said: "In regard to Dr. Nancrede's remarks, they are practically covered by what I have already said. The question of what cases should be operated upon, and by whom, is still under judgment. It would seem to be the judgment of the majority that all cases of penetrating wounds should be opened. The probe would only be used where you were prepared to operate if necessary. In many cases the ordinary signs of peritonitis are perfectly worthless. The case of ruptured intestine which died presented no apparent symptom of peritonitis.

"In those cases where intra-peritoneal injections have been made in cholera, it has been on account of the empty condition of the blood-vessels. Here it is commended for the treatment of shock, pure and simple. It is simply the application of heat. The use

of hot enemata has long been practiced in the Pennsylvania Hospital, but it is not so satisfactory as large hot water irrigations at a temperature of 100° to 110°.

"With regard to the question of mortality, the table shows the total mortality of cases reported. It is probable that the real mortality is even larger. Every successful case has doubtless been put on record, while it is likely that many unsuccessful cases have not been published. The table also includes the first cases operated upon, and I think the next three years will show a great change in the mortality. It will probably get to and remain at about fifty per cent. Many of these operations were performed without the knowledge of abdominal surgery which we now have, and many of those who operated may have had no experience with abdominal work.

"Most of these cases of traumatism involve the question of murder. If we save thirty per cent., perhaps fifteen of these will be murder cases, and on the life of each of these patients would depend that of another person, so that we should really save forty-five lives."

JOINT MEETING OF THE PHILADELPHIA NEUROLOGICAL SOCIETY AND PHILADELPHIA MEDICAL JURISPRUDENCE SOCIETY.

A joint meeting of these societies was held at the Hall of the College of Physicians, January 24, 1887. The meeting was also the stated meeting of the Philadelphia Neurological Society. The President of the Neurological Society, Dr. S. Weir Mitchell, presided.

Dr. E. N. Brush read a paper on

The Duty of the State to the Insane.

DISCUSSION.

Dr. S. Weir Witchell: "With reference to the question of joint examinations, I think that the law does not forbid such examinations. It only makes necessary a separate examination by each physician. The joint examination, with all the good that arises from it, may follow. I favor separate examinations. Then the physician makes the whole examination for himself, while in the joint examination there is apt to be too much reliance put upon the opinion of the man older in the case."

Dr. M. O'Hara: "It appears to me that the present certificate is a very poor one. It debars many from making the examination who should have a right to do so. Any one connected in the most remote degree with an institution cannot sign the certificate. Many physicians cannot be induced to go on a certificate. They are not willing to undertake the risks of subsequent prosecutions for false imprisonment of the patient. It follows, as a necessary consequence, that the practitioners who are probably most conversant with the case—for instance, family physicians—refuse, and thus the patient is handed over to strangers who are willing to take chances. Thus an early care of the insane tending to cure is prevented by the State not protecting medical men who are acting conscientiously in the line of their duty and in their highest judgment. The State should protect a physician, or otherwise give over the whole matter to a judge and jury."

Dr. T. S. Schultz: "I should like to emphasize the point in this admirable paper which refers to the present lack of accommodations for those who are not paupers, and yet are not in circumstances to pay the rates charged by private hospitals. The law requires that the State hospitals receive public patients to the exclusion of those who can support themselves when there is not room for all applicants. There are many patients whose friends can pay the moderate sum which is charged by the State hospitals, but not any more. So long as these friends refuse to be pauperized by throwing their small means into the poor-treasury, they cannot secure any accommodation. And this their self-respect, which is most commendable, prevents them from doing.

"It is, to say the least, unfortunate that such persons, who are often curable, should be crowded out of State institutions, which they assist to support by their taxes, by idiots, imbeciles, chronic and criminal insane, all beyond the reach of curative treatment."

Dr. H. C. Wood: "I feel to-night like saying a few words in regard to the protection of a class of the community in which I have a personal interest, and among which I long hope to dwell; that is, the protection of the sane. This subject has been forcibly brought to my attention during the past week. While at an insane asylum visiting a patient, the conversation turned on our lunacy laws, and the gentleman in charge stated that not long ago he had a patient liberated by the Committee on Lunacy who went home, was at once adjudged insane, and incarcerated in an asylum in another State. I happened to go from there to the house of a patient in

this city, and found the iamily considerably excited. They told me that a friend who had been in an insane asylum for a number of yeears, whose brother had killed a man and had been acquitted on the ground of insanity, had been liberated by the Committee on Lunacy. Shortly after this I met a physician in consultation, and he told me that not long ago he had sent a patient to the insane asylum, and that he had been liberated by the Committee on Lunacy. The patient then came to his office and told the doctor that he had no grievance against him for sending him to an asylum, but that he had a divine monitor in his breast which told him that the doctor was wrong in his judgment of his caae. I do not mention these facts to find fault with the Committee on Lunacy. It is far from my desire to leave such an impression. These occurrences seem to me to indicate some vital defect in the law under which that committee acts. As I understand it, there is no one on the Committee of Lunacy who would be recognized as an alienist. The law should require some one having experience in this disease to be on the Committee.

"Again, I have over and over had my attention brought to cases of dangerous lunatics at large in the community, from whom it seemed impossible to have the community protected. A year and a half ago I was consulted in regard to a gentleman who had attempted first to seduce, and, this failing, to rape his own daughter, and was only prevented by her outcries being heard outside of the house and bringing assistance. I said that the man was undoubtedly suffering with general paresis, and told the physician in charge that it was his duty to do something to protect the community. The family refused to have the man restrained. The attempt on the daughter was followed by an attempt on a stranger, which also fortunately failed. Yet the man was permitted to be at at large for months after this occurrence.

"I have been present at a number of trials in which the defense was insanity, and I have never yet seen a case in which the plea of insanity was fairly justified in which it was not equally plain that the man, before the commission of the offense, clearly portrayed that he was a dangerous lunatic. It seems to me that the law should provide that some one having authority should take hold of these cases."

Thomas W. Barlow, Esq.: "I wish to make a few remarks with reference to the accountability of physicians who sign certificates of insanity. The passage of such a law as would lessen such accountability would, in my opinion, be repugnant to the progress and spirit of the age, the progressive and humane spirit which in this State pervades the laws thrown around those deprived of their reason. For many years laws have been enacted which more closely protect the liberty of the people. In New York State, wives have been permitted to testify where their husbands have been accused of crime. In this State recently, persons accused of any grade of crime have been permitted to testify for themselves. This has been the spirit which has pervaded all laws passed within recent years. Now, in my opinion, sir, not only should the physicians be held accountable for what they do; not only should two physicians separately examine the patient who is supposed to be of unsound mind; but if it were possible to throw around such persons a greater protection, I should favor any such enactment.

In reference to the remarks of the gentleman who has just taken his seat, I would ask whether he himself knows or does not know if the woman who was recently released from an insane asylum, and whose brother was acquitted on the ground of insanity, is now a sane or an insane woman? This is the gist of the subject. He gives no instance of her present insanity; he has made no examination of her mental condition. He does not give us the weight of his authority, which is a most excellent one. It seems to me that, for his reasoning to have any weight, we should also have the weight of his opinion. In one instance in which the gentleman was an expert for the defense in the case of a man on trial for murder, the prisoner, four days prior to his execution, threw off the mask and admitted that he had been playing upon the imagination or credulity of his friends and physicians.

Dr. H. C. Wood: "I did not give the weight of my opinion in reference to the cases to which I have referred. They were simply things which had called my attention to this subject. I do say that, so far as I know, there is no way, according to the laws of Pennsylvania, to protect the community from a dangerous lunatic if his friends decline to interfere. I have seen numerous cases, one of which I cited, in which criminal assaults were at all times imminent. In regard to the case to which the last speaker has referred, we have often discussed it. The evening is short and the papers are many, and I do not propose to be drawn into a discussion of it to-night. I followed that man nearly to the gallows, and I saw no reason to

modify my opinion. In the last days of his life he was in that mental condition in which, under skilful leading questioning, he could be induced to assent to almost any proposition that was made to him."

The Care of Patients of Doubtful Mental State, and the Private Treatment of the Insane,

was the title of a communication read by John A. Clark, Esq.

DISCUSSION.

G. W. Biddle, Esq.: "The papers that have been read this evening deal measurably with a subject of stupendous interest to all civilized communities: for it may be said, without fear of contradiction, that the disease of mental alienation is one which may involve any circle and any family; and it is therefore matter of satisfaction to the members of the two societies which meet here to-night in joint convention that the subject which seems to be propounded for discussion touches us all so nearly. We must approach this subject with a good deal of calmness, and, as far as possible, with freedom from partisanship.

"The tone of both of the papers that have been read is admirable. Two prominent topics seem to suggest themselves to us for consideration after hearing them: first, what are the conditions under which a patient shall be received for hospital treatment?—what are the guards which the law throws around the unhappy subject of this treatment to protect him in all his rights, so that he shall not be dragged from his friends, his business, and his home, without a due regard to those rights? And, secondly, what is the best mode of treatment after he shall have become the subject of hospital treatment? I desire to say a very few words on each branch of this general subject.

"I wish to say, in the start, that we must not believe that we have reached perfectibility. It is hardly a century since the unhappy subject of hospital treatment was treated as a malefactor of the worst grade, chained down and subjected to every personal indignity, and if not completely mad when he entered the institution, certainly made so by the treatment pursued. It is a subject of congratulation to us as Pennsylvanians that the first attempt at humane and rational treatment was begun in this State, and has been steadily advancing until the most prominent institution in this county and State has gone as far as perhaps it is possible to go for the relief of the sufferings of those who are incurably insane. But there is a very large class who are hovering on the border-line.

"For the past twenty-five years I have watched with some care the enactments on this subject. Formerly the statement of any relative, with the certificate of any physician (not required to be verified by oath), was sufficient for admission into a hospital for the insane. There were grave objections to this. The reader of the first paper has said that Lord Shaftesbury asserted that, out of one hundred thousand cases, he had never known a man or a woman introduced as the subject of hospital treatment who was not a proper subject for such treatment. I see just opposite me a gentleman who will verify all that I say when I state that, fifteen or sixteen years ago, a man as sane as any one in this room was sent to an insane asylum on a physician's certificate. He was promptly discharged by a late chief justice on a writ of habeas corpus. He was, to use a euphemistic expression, the victim of the hallucinations of his family: he was under no hallucination. These cases do occur, although they are undoubtedly rare. I think that it was in consequence of that occurrence that the Act of Assembly was passed requiring the certificate of two physicians to be made within a week after a personal examination, the examinations to be made separately and verified by affidavit before a magistrate of the county. There is nothing to exclude a joint examination. The object of the law was to throw each of these gentlemen on his own responsibility by requiring his separate affidavit, and surely no objection should be made to that. I know of no instance in which a physician has been brought in jeopardy of his pocket by making a certificate in good faith. It is possible, indeed probable, that there are such cases with which I am not familiar, but I doubt if they often occur. The certificate is in the nature of a privileged communication, and, if made in good faith, the provisions of the act of 1883 should protect him if he has unfortunately fallen into error. He has done the best he could, and that is all that any one can do. Everybody makes errors of judgment every day of his life. I do not know, as at present advised, that we can go much farther in this direction. The medical profession has always been the pioneer in works of beneficence. A distinguished judge once said publicly that physicians did more good charitable work without expecting or receiving any earthly reward than any other body of men that he had ever met. The black heeps

among them constitute but a small percentage. We must rather look, therefore, to the medical profession for improvement in this respect. The legislators of the State and the legal profession are always glad to receive suggestions from it. The law at present may be somewhat crude, but it is the best that has been suggested."

Periscope.

Boric Acid.

Dr. J. T. Searcy thus writes in the *Alabama Med. and Surg. Jour.:*

Boric (or boracic) acid fills a place as an antiseptic that, for cheapness, pleasantness, ease of application, and efficiency, I do not think is fully appreciated. In many particulars and in many cases, I find it serves such a purpose better than iodoform, or the solutions of sublimate or carbolic acid, that are more frequently used. Its usual harmlessness to the structures of the body, and at the same time its great germicide properties, render it the efficient remedy it proves to be in a great number of cases.

The best shape in which to use it is as an impalpable powder. It can be obtained in this form from the leading druggists. Care should be taken to have it chemically pure, and thoroughly comminuted, else it will prove irritating to some more sensitive surfaces, and disappoint in its antiseptic qualities.

An ordinary tin pepper-box is a good instrument to apply it with. Such a pepper-box, filled with the powdered acid, kept in every surgeon's or practitioner's office would be found of almost daily use and of great service.

Open wounds, before they are closed and afterward, can be freely dusted over with the powder, without any smarting or any constitutional septic effects to follow; and it can be used in conjunction with the other antiseptics if desirable. I frequently bathe over the surfaces with solutions of sublimate or carbolic acid, and while still moist I make as much of the powdered boracic acid stick to them as possible before I put on my dressings. This can be done with either changeable or permanent dressings. The coating of the acid underneath is melted by the natural secretions of the part, or by the discharges from the wound or sore, as it is needed, and renders them thoroughly antiseptic and disinfected. The cost and the offensive smell of iodoform make it objectionable for this purpose. In many cases gangrenous and sloughing parts can be rendered almost odorless with the boric acid.

I have seen a foot crushed in a railroad accident, the toes afterward sloughing off, put up with an ounce or two of this powder underneath the dressings, that were kept on several days until the perfect lines of sloughing demarcation were established, with no appreciable smell in the room, little or no discharge, and no fever or constitutional symptoms—all due to the excellent antiseptic qualities of the boric acid. Whenever there is offensiveness in any sore, ulcer, or slough, a free coating of the boric acid renders it more pleasant than anything else. Cancerous and other ulcers are benefited by it, in combination with iodoform or not. I have poured it into the vagina in cases of cancer of the cervix, a teaspoonful at a time, with the effect of retarding the growth and rendering the offensiveness of the disease much more endurable. It makes an excellent injection for gonorrhœal inflammations in the strength of ten grains to the ounce of water for the urethra, and half an ounce to the pint of hot water for the vagina. Very few times, even applied in quantity, have I seen it prove irritating or hurtful to inflamed surfaces. Eczema, both in its moist and in its dry stages, is helped by it, as a rule. Dusted finely on itching surfaces, it proves usually a very grateful application. It is almost a specific for ring-worm; moisten the surface first, and with the wet hand or a piece of sponge rub the powder into the skin firmly once or twice a day. All itching is soon allayed, and the part gradually gets well. It is also an excellent article on the toilet stand. Persons troubled with offensive secretions of the axillæ or the feet will find this a very efficient and pleasant application. One part of powdered boracic acid to two parts or four parts of vaseline makes an excellent "healing salve." I sometimes make a combination of iodoform, one part; boric acid, two parts; and vaseline four parts, for venereal sores, with success.

These suggestions will show the variety of ways in which it can be used. Other combinations and applications will readily suggest themselves.

A Case of Locomotor Ataxy with Several Unusual Symptoms; Remarks.

Dr. Hale White thus writes in the *Lancet:*

There are few diseases which present such a multiplicity of symptoms as are found in locomotor ataxy, of which the following case is an example. The prognosis is very unfavorable, but the course of the disease may be spread over a long period (even thirty years, according to Bristowe), the patient, however, making frequent calls on the physician for relief of symptoms. Although, as Dr. Hale White observes in his remarks, death is generally due to inter-current disease, it may also be caused by implication of the muscles of deglutition, paralysis of the laryngeal muscles, renal disease, secondary to vesical mischief, or even to bedsores. We refer our readers to the remarks appended to the case.

Alfred P., aged fifty, was admitted on June 10, 1886. He was in Philip ward, under Dr. Fagge, in 1883. An old report states: "He has been the subject of chronic rheumatic pains for many years. Three or four years ago he suffered from indigestion; three months ago he had a sharp attack of pain in the stomach, lasting all day, and accompanied by vomiting. These attacks have become more sharp and frequent lately. The pupils are unequal, the right being larger than the left. They do not react to light or accommodation. He can stand with his eyes shut; he has paralysis of the right external rectus and diplopia; both discs show a white margin and venous pulsation. The patellar reflex is absent. The superficial reflexes are normal. Sensation: Occasional numbness of legs and arms. He has shooting pains starting in the toes and running up the legs. He has girdle pains at the lower part of the thorax, the ring being about four inches across. He has numbness over this area and upwards to the shoulders behind, and down the extensor surfaces on both sides as far as the hands; he has also numbness of the face and head. Twenty-one days after admission he suddenly had transitory pains of the right upper limb. The stomach had sometimes to be washed out. He can turn and walk easily along a chalked line." The old report, to which all the above refers, is headed "Early Tabes Dorsalis, with Gastric Crises." He has been getting worse since; has had much difficulty in breathing; he went to St. Bartholomew's Hospital last January, stayed there three months, and was tracheotomized for this trouble.

State on Admission.—The abductors of the vocal cords are quite paralyzed, and they are so close together that they leave a median chink no wider than the thickness of a sheet of note paper. They appear healthy, but are quite immovable when he speaks or breathes. He wears an India-rubber tracheotomy tube with an opening on its upper surface. He speaks, very hoarsely and indistinctly, by putting his finger over the tube. His hearing is preternaturally acute. His sight is bad; he wears convex glasses; has conjunctivitis in both eyes; the right pupil is the larger; pupils do not react to light or accommodation; there is no strabismus, but there is complete ptosis of the right eye, and there is hemiatrophy of both discs. He cannot stand with his eyes shut, and walks with a slightly ataxic gait. His muscles are very little wasted; there is no rigidity. Tendon reflexes all absent, superficial ones diminished. He very rarely gets gastric crises now. The anæsthesia, numbness, and the girdle and lightning pains remain as before. All his joints are healthy. His tongue is normal. Only two teeth are left in the upper and one in the lower jaw; some of the teeth have been extracted, others have fallen out, and one or two have broken off near the root; those in the mouth now are not decayed, but are quite loose. The alveolar processes of the jaws are quite atrophied. He has a sensation as if he always had food in his mouth. Bowels irregular. Occasional catheterization is required. No sexual disturbance. The patient seems to be deficient in power of smell.

The Inequality of the Pupils in Various Diseases.

Dr. Pasternatski, who has been working in Professor Chudnovski's clinic in St. Petersburg, has published in the *Vrach* an account of a number of observations he has been making on the inequality of the pupils in various diseases, thus carrying out a suggestion made by his chief in a work on the methods of examining medical patients, published in 1883, in which he expressed an opinion that careful examination of the pupils would lead to interesting results. Dr. Pasternatski examined a number of methods which have been proposed, but did not find any of them suitable for his purpose, and ultimately a much simpler plan, suggested

by M. Follin, was adopted. This consists in bringing a catheter gauge card close to the eye, and comparing the size of the pupil with the apertures in the card. By this means the size of the pupil in millimetres can be ascertained with a degree of accuracy sufficient for the purpose. It is important to make the observations in the shade, for the difference, when there is any, between the diameters of the pupils increases as the light is diminished. The best method of conducting the examination is to close the eye which is not being observed, for this causes a slight increase in the diameter of the pupil of the latter, as was, indeed, remarked by Hippocrates. It was found, for example, in a case in which this was tested, that when both eyes (being in the shade) were fixed on an object at a distance, the diameter of the right pupil was $5\frac{1}{3}$ mm., and that of the left 6 mm.; when, however, the eye not under examination was covered up, the diameters increased to 6 mm. and $6\frac{2}{3}$ mm. respectively. As to the diseases in which inequality of pupils has been observed, Dr. Pasternatski quotes a number of cases mentioned by continental physicians; also one of aneurism shown by Professor Gairdner to the Edinburgh Medical Society; as well as two reported by Professor Finlayson in the *Lancet* of January 3, 1885, in both of which aneurisms were found at the necropsy. His own observations gave the percentage of cases in which inequality was found in various diseases as follows: Croupous pneumonia, 85; heart diseases and aortic aneurisms, 61; pleurisy, 52; chronic catarrhal pneumonia, 38; acute articular rheumatism, 25; catarrh of the respiratory passages, 25; scurvy, 16; typhus, 16; recurrent typhus (relapsing fever), 15; abdominal typhus (enteric fever), 13. Inequality of pupils was also found in half the cases of catarrhal and hepatic jaundice and renal colic. The largest percentage occurred in croupous pneumonia, and study of the cases showed that the position and stage of development of the disease has a remarkable effect upon the pupils. At the very commencement the pupil on the same side as the affected lung is, as a rule, larger than the other. The difference generally increases with the lung inflammation, reaching its height on the third, fourth, or fifth day; before the crisis the difference decreases, sometimes even disappearing. Afterwards, during the stage of resolution, a difference is again manifest, the pupil on the affected side being now contracted. Not only do the pupils in pneumonia differ in size, but also in sensibility to light. Speaking generally, the author's observations lead him to believe that inequality of pupils is most frequently met with in those internal diseases which not only affect the system generally, but which, like pneumonia, pleurisy, and hepatic and renal colic, are definitely localized as well. It is also very usual in heart diseases and aneurism, but comparatively rare in scurvy and infectious diseases such as typhus, and when it does occur in these it is generally consequent on some complication.

Brain Surgery.

The *Med. Press*, January 26, says:

Facts do not appear to favor the prosecution of this branch of the surgical art, and the more they are looked into by the light of results the less do they support the views of the F. R. S., who painted them in such glowing terms recently in a contemporary. Unfortunately for that (his, F. R. S.'s) view, says Dr. Goodhart, in the Pathological Society's Transactions, "I had in my mind another case in which, according to the diagnostic skill of Dr. Ferrier himself, a cerebral tumor was judged to be a fit case for the attempt at its removal. The man died before the attempt was consummated, and the tumor was found to occupy the entire thickness of the anterior third of the affected hemisphere. *This is the way in which* (italics ours) *most of these cases reject the advances of surgery.* Extensive disease in the white matter gives so little evidence of its presence. For the last thirteen years I have been making post-mortem examinations at Guy's Hospital, and during that time, although I have come across many cases of cerebral tumor, I do not remember to have seen a single case in which the tumor was at the same time *accessible* and so *localized* as to be capable of successful surgical attack. . . . When, therefore, I read that the case to which I have alluded has opened the door to successful treatment of scores of similar cases, I can only say that a consideration of all the facts and particulars of that class makes one very doubtful as to the accuracacy of F. R. S.'s judgment. I am the more inclined to take the opposite view, viz., that it is very doubtful whether in the region of cerebral tumors other than inflammatory, *surgery has any future worth mention before it.*" So speaks an able pathologist, as well as a practicing physician of specialized experience on the point, and we trust that the authorities of our hospitals, surgical and otherwise, will take stock of these statements, and either prohibit entirely or reduce to a minimum

these ingenious but withal useless opeaations. Assuredly, if they do not, some irate friend or relation will interpose and call them or their operator to a severe account. Woe be to him who ignores such teaching and such facts as we have just reproduced! However disinterested he may appear to be, no jury could "find" for him in face of such damning evidence as this of Dr. Goodhart's undoubtedly is. It more than upholds Surgeon-General Gordon's inquiry as to the *cui bono* of such wild surgery or more worthless experimentation. Confirmatory also of this view, we have before us opinions of the Committee on "Morbid Growths or Intra-cranial Tumors" as follows: "The Committee felt that it would be impossible to pass over the question of surgical treatment in intra-cranial growths. Yet out of the fifty-four tabulated cases *two only seemed suitable for removal.* Again, "the fact that intra-cranial growths may exist in certain parts without giving rise to symptoms referable to such parts, their tendency to compress and displace without destroying, and lastly, the pressure they exert on remote parts *very often render their localization a matter of pure conjecture.*" Verily Dr. Gordon may again repeat his *cui bono*, without any expectation of getting it satisfactorily answered, and if these several statements are—as they undoubtedly are—true, then might Ferrier as well have been beating the air as boring holes into the crania of monkeys, or cutting slices out of their contents.

Muscular Atrophy Caused by "Hydro-Myelitis."

Dr. C. Wallis, of Stockholm, reports an interesting case occurring under his care in the Sabbatsberg Hospital, where a peculiar affection of the spinal cord, which he calls hydro-myelitis, had produced progressive atrophy of the muscles. The patient, a peasant aged thirty-eight, was admitted for empyema on the right side, of which he died in a week's time. He had noticed for some eighteen years a gradual impairment of the power of his right hand, and for seven or eight years of that of the left. The right hand was flexed (*in Krallenstellung*), with atrophy of the interosseous, flexor brevis, and opponens pollicis. A similar condition existed in the left hand, but to a less marked degree. The muscles of the right arm and shoulder were also slightly atrophied. At the necropsy, besides the empyema, atrophy of the muscles of the hand and forearm was found, and in the same condition was also present in a marked degree in the deltoid and serratus magnus on the right side. Microscopical examination showed that in most of the localities where atrophy existed the muscular fibres had lost their transverse striated appearance, and that they were undergoing fatty degeneration. A centimetre below the medulla oblongata, the central canal of the spinal cord began to be dilated, attaining opposite the roots of the second and third cervical nerves a diameter of half a centimetre. The anterior cornua were greatly atrophied; the posterior cornua were of an abnormal shape, and displaced by the increased size of the canal, but were not atrophied. The distended condition of the canal continued without alteration along the whole of the cervical portion; below this it began to diminish, and at the same time the atrophy of the anterior cornua became less marked, but it was only in the lumbar portion that the cord presented its normal characters. The canal contained a transparent and very fluid liquid and its wall consisted of a firm white membrane a millimetre in thickness.

Use and Abuse of Passive Motion.

Dr. Henry B. Sands thus concludes an article in the *Med. News:*

To sum up what I have said, I am not an advocate of passive motion, except under the restrictions which I have endeavored to define. I believe that when practiced without discrimination, it will often be unsuccessful, and sometimes injurious, by inducing an increased inflammation. I am certain that the severe forms of ankylosis and of fixation of tendon are frequently due to this disease, and that the inflammation will be aggravated by employing passive motion before the active symptoms have disappeared. The idea that motion will always prevent ankylosis is a fallacy which is contradicted by common experience. I have performed the operation of incision of the elbow for the cure of true ankylosis, and I have seen operations performed by others, during which, perhaps, too little bone was taken away; and, in spite of the early and diligent use of passive motion, the stiffness has returned, bony consolidation has recurred, and the operation of excision has had to be repeated. But motion may be successfully employed as a means of causing a bony deposit to take place. It is a well-known fact, that in many instances of ununited fractures of the thigh or of the leg, bony union may be determined by the inflammation which is

got up by making forcible motion of the fragments, or by causing the patient to walk about upon the injured limb, with the view of pressing them against each other. On the other hand, by operating according to modern antiseptic methods, which tend to prevent inflammation, partial incision of even so intricate a joint as the elbow may sometimes be performed without any impairment of mobility. I have brought the subject of passive motion to the attention of the society because it is one of great practical importance, about which surgeons are frequently consulted, and about which there may be honest difference of opinion; but, as I mentioned in the beginning, I should be glad to change some of my present views, if others could be advanced which are sustained by evidence that appears to me to be clear and trustworthy.

Nephrectomy for Scrofulous Disease.

A very successful case of removal of the kidney for scrofulous disease was brought before the Glasgow Medico-Chirurgical Society recently, by Mr. Henry E. Clark, one of the surgeons of the Royal Infirmary. The patient, a married woman of 26, has gradually developed the signs of abscess in the left loin, and as the urine contained pus and epithelial debris, this was diagnosed as being a renal abscess. The kidney was incised in January, 1886, and about a pint of pus evacuated; but the the sinus continuing to discharge and other abscesses forming in the kidney, extirpation of the organ was decided upon. This was done in August last, by the lumbar incision without any difficulty, the only incident worthy of note being the slipping of the ligature at the time of separation of the kidney from its pedicle. The patient made rapid recovery, and is now in perfect health with a normal excretion of urine. Mr. Clark especially dwelt on the importance of the evidence obtained by the use of the urethral catheter, as showing the other kidney to be sound, and showed that in the female the introduction of a catheter into the ureter was safe, easy, and satisfactory. He referred to the statistics of extirpation for scrofulous disease, and objected to the conclusion of Gross that the ventral was safer than the lumbar incision in such cases. He also made some observations on the best position for the lumbar incision in relation to the last rib and pleural cavity. We congratulate Mr. Clark on the success of this very important operation. Successful nephrectomy marks a new era and a new triumph in surgery. M. Paul Segond gives the particulars of two successful nephrectomies, the one for suppurating hydronephrosis, and the other for painful floating kidney, in the *Annales des Maladies des Organes Génitos-Urinaires*, for last month.

Unusual Site of an Hydatid Cyst.

A case of hydatid of the scrotum came under the care of Mr. Philip E. Muskett in the Sydney Hospital during the course of last summer, and as this is an example of a very rare condition a brief note will be of interest. The patient, aged twenty-five, had been in Australia since he was three years old, and in a sheep district where the water was very bad for four years before the swelling appeared; this was first noticed eight years before he came under treatment. During that time it had been tapped twice, and on the second occasion also injected with iodine. When admitted to the hospital "there was an intra-scrotal tumor, about the size of a large emu egg, on the right side. It was smooth in outline, and its general contour nearly oval. The tumor was tense and dull on percussion, but gave to the fingers on palpation the sensation of fluid within. There was no impulse on coughing, and it was irreducible. The position of the testicle at its posterior part was made out by the presence of testicular sensation. The cord could not be clearly defined at the upper portion of the swelling. Light was transmitted by the ordinary manner of procedure, and, finally, the history had been that of an eight years' growth: painless except from its mere weight." The cyst was tapped on the day following admission, and about an ounce of "serous-looking fluid" of pale yellowish tinge evacuated. Suppuration followed this tapping, and thirteen days later about six ounces of purulent fluid were drawn off. After this pus drained away from the puncture for eleven days, then a hydatid sac partly forced its way out, and was partly extracted through this opening. The sac was grayish in color, translucent, and elastic, and in its sunken condition would about fill an egg-cup. The swelling gradually subsided, the sinus closed, and the patient left cured.

—The Queen has conferred upon Mr. C. H. Newby, F. R. C. S. Eng., of Southsea, the decoration of the Red Cross, in recognition of his services to the sick and wounded Servians in the late campaign.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A new and interesting branch of medical history is opened by Dr. Horatio R. Storer in a reprint before us, entitled "The Medals, Jetons, and Tokens Illustrative of Obstetrics and Gynecology." He describes a large number, many of great rarity, and shows how full of information this line of investigation may prove. Copies may be obtained from the author, Newport, R. I.

——Dr. George Strawbridge, of this city, has brought out the statistics of 261 cases of cataract extraction, forming an instructive series of observations.

——A very valuable contribution to the medical literature of this State is a monograph by Dr. William Pepper, of this city, entitled "A Contribution to the Climatological Study of Phthisis in Pennsylvania." It contains a large mass of statistics, several maps and charts, and a careful discussion of the results obtained. Published by D. Appleton & Co., New York.

——The scientific achievements of Dr. Benjamin Rush meet a sympathetic and appreciative critic in Dr. Charles K. Mills, who in his printed address on "Benjamin Rush and American Psychiatry," clearly sets forth how much this country and science at large owe to this able man.

——An article by Dr. L. Webster Fox, and Mr. George M. Gould, of this city, discusses The Reason Why the Retina is Insensible to the Ultra-Violet and Infra-Red Rays of the Spectrum. The explanation is ingenious.

——"Physical Education and Personal Hygiene," is the subject of an address by Dr. Wm. H. Shipps, of Bordentown, N. J.

——A Report on the Removal of the Uterine Appendages in Nine Consecutive Cases, Dr. Mary A. Dixon Jones, makes an interesting reprint.

——In a reprint entitled "Hysterorraphy," Dr. H. A. Kelly, of this city, describes a number of cases of this operation.

——The statistics of a year's work in ovariotomy are laid before the profession by Dr. Wm. Goodell, of Philadelphia. There were 29 cases in all, and the discussion of the various symptoms they presented, etc., is highly instructive.

BOOK NOTICES.

A Treatise on Simple and Compound Ophthalmic Lenses: Their Refraction and Dioptric Formulæ, including tables of crossed cylinders and their sphero-cylindrical equivalents. By Charles F. Prentice. Cloth, 8vo.; pp. 44. James Prentice & Son, New York.

This essay treats of refraction, prisms, simple and compound lenses, asymmetrical surfaces, and adds tables of value to the optician. It has interest to all opticians and ophthalmic surgeons.

Wear and Tear; or Hints for the Overworked. By S. Weir Mitchell, M. D., LL. D., etc. Fifth edition. Cloth, 8vo.; pp. 76. J. B. Lippincott & Co.

This popular appeal for a wiser physical culture evidently has not fallen upon deaf ears. It is gratifying to observe that a fifth edition has been demanded, which now appears with a thorough revision from the hands of the distinguished author. May its earnest words be not only read, but heeded by the thousands in our land whose happiness depends on the better observance of the laws of life.

Nervous Diseases and Their Diagnosis. By H. C. Wood, M. D., LL. D., etc. Cloth, 8vo.; pp. 501. J. B. Lippincott & Co., 1887.

The object of the author in this work is especially "diagnostic neurology." He concerns himself with the phenomena produced by the nervous system in so far as they bear upon the recognition of the causes of these diseases. With their treatment he does not concern himself.

The plan adopted is not that usual in such treatises, but one which has been evolved by a number of years' duty as instructor in clinics where this class of maladies was common. Beginning with the varied forms of paralysis, he passes to motor and then to sensory symptoms, concluding with a discussion of those interfering with memory, consciousness, and intellection. This scheme, it will be seen, is strictly symptomatic, and as such, has all the practical convenience of symptomatic schemes in general, and is exposed, as they all are, to the charge of inferior scientific precision.

The details are worked up from the stores of an ample clinical experience rigidly analyzed, and from a wide reading of the literature of the subject. As a whole, the work is one which cannot fail to be of great service to the practicing physician.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

IRRITABLE HEART.

When an individual suffers from palpitation, the disease is called "irritable heart," if no organic lesion be present accounting for the disturbed function. Disturbed innervation of the heart, "nervous heart," are other synonymous terms. Very few, however, know that there are various kinds of disturbed heart functions, and in this connection it will be interesting to read the article of Dr. K. Dehio on nervous palpitation, which this physician published in the *Petersb. Med. Woch.*, 1886, No. 31.

The purely nervous disturbances of the functions of the heart, according to D., are best divided into angina pectoris, nervous palpitation, and tachycardia. In the first the disturbance of sensation, the subjective feeling of pain, stands in the foreground; in tachycardia we have a motoric disturbance, an increase in the frequency of the heart contractions objectively demonstrable; while nervous palpitation is in the middle between the two extremes, for here we have as well the subjective sensation of the beating and the action of the heart, as the augmentation of the contractions of the organ as determined by objective examination. D. made a series of sphygmographical examinations of persons suffering from nervous palpitation, and found that various types and groups of palpitation exist. In the one kind we have a more rapid palpitation and more rapid ventricular contraction, conditions which may be artificially produced in healthy persons by the subcutaneous administration of atropia. In a second group of cases only the frequency of the heart *choc* is increased, while the vascular tonus is diminished and the arterial pressure in general is lowered, conditions which may be developed in the healthy by the inhalation of nitrite of amyl. The first group D. believes to be due to a transient paresis or diminution of the tonus of the medullary inhibitory centre, the paresis appearing in paroxysms, while in the second group, besides the morbid state just mentioned, the medullary vaso-motor centre also becomes transiently paretic. The abnormal sensations which so often accompany palpitation, as præcordial fear, gasping for air, tinnitus aurium, formication in the extremities, etc., seem to be present only in those cases where the vascular tension is apparently diminished; they may be explained by the great retardation of the circulation, which again is due to the general lowering of the vascular tonus.

The recognition of the two groups, as also that of the three kinds of functional dis-

turbance of the heart, is not without its practical value, for according to the kind of palpitation present our therapeutical efforts must necessarily vary. The facts elicited by D. also explain the diversity in the remedies recommended for palpitation of the heart, some of which, as digitalis and aconite, wine, nitrite of amyl, and the bromides, are diametrically opposed to each other.

ON SUBSTITUTION BY DRUGGISTS.

Our attention has been called by several of the leading wholesale druggists to the frequency with which prescription clerks substitute the preparations of one house for those of another in cases where a particular manufacture has been specified on the prescription. The ordinary phrase is, "Oh, they are all the same: the one is as good as the other." In this way the purchaser is placated and the vendor succeeds in his sale.

That this is unfair both to the purchaser and to the manufacturer is plainly evident. The modes of preparation of extracts, tinctures, etc., differ materially, even when they are based on the same formula. Some houses always use the finest grades of raw material; others always use the cheapest, without reference to any other characteristic. Experience goes a long way to improve the details of methods, and experience varies with every person and firm. Many manufacturers have no hesitation in using adulterants; others would scorn to adopt this means of cheating. All these are facts well known to anybody who knows the drug trade at all, and they are all excellent reasons why a prescription druggist should scrupulously respect the directions of a physician to use only the preparations of the house specified, and no others.

Several instances have been brought to our knowledge recently where such directions have been systematically disregarded. It may be asked, what remedy can be suggested? There is none but a rigid insistance on the part of the prescriber that his directions be obeyed. A general recognition of the importance of orders of this nature will bring good results.

A-KAWA-RESIN OR LEWININ.

Dr. Lewin, the physician who introduced the hypodermic injection of corrosive sublimate for the cure of syphilis, has recently discovered that the a-kawa-resin acts as an excellent local anæsthetic. Dr. Randolph investigated its effect in conjunctival diseases. On account of the irritation which it causes, he first made use of a solution of cocaine, which he applied locally, and he then found that the a-kawa-resin prolongs the action of the cocaine. He proposes the name Lewinin for it.

The remedy will probably always have only a limited field of usefulness. First, because of its irritating qualities it cannot be employed on sensitive parts, and they must be previously anæsthetized by some other remedy, mainly cocaine. Then the action of Lewinin is a purely superficial one, and extends only to the surface to which it has been applied. It has, however, the advantage of acting when locally brought in contact with the tissue to be anæsthetized, while cocaine must be subcutaneously injected. Unless further observations augment its field of action, its usefulness will be limited to cases where we desire to prolong the short local anæsthetic effect of cocaine.

SYPHILIS OF THE EAR.

That hereditary syphilis may localize itself in the ear is not generally known. Dr. Wilson (*Ztsch. f. Ohrenheilk.* xv., p. 268) reports the cases of three children. In a family, where the father has surely been syphilitic, and where suspicion existed that the mother was also infected, three of five living children suffered from purulent inflammation of the middle ear. The disease in all of them developed a few months after birth. The oldest child, in whom the dyscrasia was not recognized, became a deaf mute. No specific treatment has been given in the case. In the second case the purulent discharge ceased, and a complete cure was established by the use of mercury; followed later by iodide of potash. In the third child the purulent discharge also stopped after the liberal use of mercury; but later, when the child became sick with measles, a purulent otitis media again set in. Dr. W. believes that the ear inflammation in these cases was a local manifestation of the inherited syphilitic taint.

PREVIOUS HABITS AND COCAINE.

Whoever reads carefully the various reports regarding the special effects of cocaine as they appear in the medical journals, will have discovered long since that some observers deny the presence of any untoward symptoms, while others just as stoutly maintain the injurious side-effects and consequences of the administration of cocaine, even if locally employed.

It seems to us as if the strength of the solution, the manner of using it, and the place of application, decidedly exert some influence on the peculiar properties which cocaine develops when given to some individuals. That, however, another important factor also plays a role, and perhaps the main one, in this respect, has been proved by observations recently made by Dr. Ziem (*Deutsche Med. Wochensch.*, 1887, No. 2).

Z. had a patient who suffered with swelling of the Schneiderian mucous membrane of the nose, and with purulent discharges from the latter. The man, æt. 45, apparently robust and otherwise healthy, had formerly been a heavy drinker and an inveterate smoker (which he still was), and had also been infected ten years before by syphilis. For the purpose of a posterior rhinoscopy, Z. applied a two per cent. cocaine solution. Immediately after the patient's face became very pale, he complained of nausea and a feeling of weakness, symptoms which remained the whole of the afternoon.

On account of similar observations, which Z. made on other patients, he advises physicians carefully to inquire into the previous history of patients on whom they desire to make a local application of cocaine, for the existence of syphilis and the abuse of tobacco and of spirituous drinks seem to predispose such individuals to the injurious after-effects of cocaine.

Notes and Comments.

Atrophic Orchitis.

Inflammation of one testicle often occurs without any apparent cause. As a rule these inflammations, which are rarely as severe as those accompanying gonorrhœa, generally are worse in their consequences than those last mentioned. Dr. S. Róna (*Monatsch. f. Prakt. Dermat.*, 1886, No. 11), reports the case of a young man, whose left testicle suddenly became inflamed. No cause could be discovered except a general rheumatic tendency. The epididymis and the seminal cord remained perfectly intact. The inflammation itself offered nothing characteristic; it was not very severe, and seemed to yield easily to the antiphlogistic treatment. After the acute symptoms had subsided R. strapped the testicle. One year later the testicle had so atrophied that nothing of it remained but a round body, the size of the smallest marble, about as large as a buckshot, while the right testicle had enlarged to fully its double size, without otherwise changing its normal conditions. The sexual powers were the same. R. is of the opinion that some of these inflammations carry the atrophic character with them from the very start, and he thinks that the strapping had nothing to do with bringing about the atrophy, as the swelling lessened immediately after the strapping, so that the bandage only caused an absorption of the fluid secreted in the tunica albuginea, without compressing the orchis itself.

Oxalic Acid as an Emmenagogue.

Dr. Poulet, in the *Gaz. Hebd.*, 1887, No. 1, highly recommends oxalic acid as a remedy far superior to any other as an emmenagogue. Its field of action, however, seems to be limited. For instance, it has no effect on the neuralgic pains from which some women suffer, whose menses are otherwise normal, nor does it influence amenorrhœa in the least when this is due to some organic disease of the female sexual organs. But whenever the menses do not appear in consequence of some functional disturbance, or when they are retarded by some transient cause, as chilling of the surface, catching cold, etc., oxalic acid is the remedy par excellence, which will rapidly re-establish the flow.

The way in which P. administers the remedy is as follows:

℞.	Acid oxalici,	gr. xxx.
	Aquæ distillat.,	f. ℥ vj.
	Syrup cort. am.,	f. ℥ ij.
M.	S.—A tablespoonful every hour.	

The remedy should be administered at the time of the usual appearance of the monthly period, and care should be taken that no incompatibles, as magnesia, lime, etc., be given at the same time.

Primary Nerve-Suture.

Mr. Herbert Rowe had recently sutured the ulnar nerve with a catgut suture (*Brit. Med. Jour.*), in a case in which both ulnar artery and nerve were divided, soon after the accident. Two days afterwards, there was a diminution of the numbness. In four days the sensation was the same, but there was some slight movement in the muscle. At the end of one month, sensation was but slightly impaired and motion was definite, but not perfect. Shortly afterwards, the man resumed his occupation. Mr. Rowe referred to cases reported by Nélaton and others, in which sensation partly returned at the end of the second day, recovery taking place at the end of a week. In a case of

primary suture of the median recorded by Lauquier, recovery began on the day of operation. He compared the rapid restitution of function in primary suture with the later development in cases of secondary suture, and referred to a case in which the sciatic nerve was sutured by Mr. Wheelhouse, perfect function being restored only after several months.

Mr. Wheelhouse said that nerve-suture was established as a satisfactory operation, whether primary or secondary, bnt in one case of the latter he had known the effect delayed for three months.

Intestinal Obstruction.

Dr. Totherick read a paper on the difficulties in the way of the diagnosis of this condition, before an English medical society, remarking that in that respect age had an important bearing, as in the obstruction of childhood the causes were rarely more than two, namely, intussusception and peritonitis. He, however, related a remarkable case in which all the symptoms of obstruction and peritonitis were present, and which ran to a rapidly fatal termination, and on post-mortem examination neither one nor the other was found, but the cause was discovered to be acute caries of the dorsal vertebræ with commencing purulent formation in the various organs. In aged people also the causes were generally confined to two ; namely, impaction of fæces and malignant disease. In middle age any of the causes might be in operation, the most common being impaction, which should be treated by repeated enemata of water or oil. In acute eases in which the diagnosis was uncertain, but the fatal termination sure, exploration by abdominal section was recommended. Of all drugs, opium was the most generally useful, and in cases of impaction, saline aperients might do good. In simple inertia of the bowels from repeated constipation and over-distension, he had found faradism very useful.

Pernicious Anæmia.

Before an English Medical Society, Mr. Bates described a fatal case in a patient aged 49. The principal symptoms were shortness of breath and attacks of vomiting and diarrhœa ; there was also an attack of jaundice. At the necropsy the liver was found slightly fatty, and the stomach walls were very thin, but had not yet been microscopically examined. Death took place after twenty-four hours of unconsciousness. He described another case of the same kind, in which also there had been jaundice before death ; the stomach also was very thin.

Dr. Black spoke of the advantages of using alteratives in the treatment of anæmia.

Dr. Allbutt referred to the definite character of idiopathic anæmia, as accompanied by extravasations into the retina, and in curable cases remedied by arsenic rather than iron.

Mr. Jessop spoke of three cases he had seen, in all of which the patients lived in houses much exposed so sewer-gas.

Dr. Eddison questioned the use of the term pernicious anœmia as applied to the case. In every case he had seen the blood-corpuscles were distorted. He thought many were cases of ague or syphilis.

Cod Liver Oil.

M. Carles, Prefesseur Agrégé at the Faculty de Médecine of Bordeaux, has recently re-affirmed (*Brit. Med. Jour.*) that the cod liver oil which is lightest in color is the purest and the most easily assimilated. The deep color frequently seen in cod liver oil is owing to more or less putrefied livers having been used. M. Hogg, a Paris chemist, had already stated, in a report read before the Academy of Medecine, that the natural oil obtained from the cod's liver is almost colorless and tasteless; that it smells of fresh fish, and that cod liver oil which is brown in color, has been prepared from livers in a state of putrefaction. M. Lesueur, Chef des Travaux Cliniques of the Paris Faculté de Médecine, confirms these statements, and testifies to the superiority of M. Hogg's cod liver oil obtained in his fisheries off Newfoundland by a process of his own. M. Lesueur states that this oil contains nearly double the active properties of the cod liver oil generally sold, and that it is free from the disagreeable taste and odor of these oils. Different preparations have been invented to replace cod liver oil, but without success.

The Operative Treatment of Intercurrent Disease in Tubercular Patients.

Before an English medical society, Mr. Bruce Clarke read a paper on this subject. After briefly discussing the nature of tuberculosis and its dependence on a specific bacillus, the author proceeded to show that it was almost impossible to remove by a surgical operation the whole of the bacilli that had found their way into the body. The local manifestation was all that could be got at. It was clear, therefore, that an operation could only aim at removing a growth which

was causing so much constitutional disturbance as to prevent the recuperative powers of the patient and the physician's remedies from exercising a due influence on the course of the intercurrent disease. After relating several cases of his own and of other surgeons, in which such operative treatment had been practiced with more or less favorable results, and after showing that such cases healed with success and ease, the author concluded by asserting that surgical interference was only justifiable when all attempts at cure without the knife had been tried and found wanting.

On Removal of the Uterine Appendages.

To the Edinburgh Medico-Chirurgical Society, recently, Mr. Skene Keith showed interesting specimens of diseased ovaries and fallopian tubes, removed by operation, and thereafter read a paper on "The Removal or the Uterine Appendages," in which he detailed the results of his own and Dr. Thomas Keith's operations in this department. Mr. Keith expressed the opinion that the commonest cause of disease in these organs is laceration of the cervix. He thought that if greater attention were paid to the primary lesions, there would be less necessity for operative interference later. Removal of the appendages had, without doubt, been resorted to too frequently. He did not think that gonorrhœa was a frequent cause, at least not so far as the cases which came to him were concerned. In reply to Prof. Annandale, Mr. Keith said he did not think inflammatory affections of the parotid were commoner after uterine and ovarian operations than after other operations. He had not met with a case of suppuration of the parotid.

Case of Plastic Operation for Ectropion.

Mr. Davies-Colley showed a case of ectropion, following necrosis of the upper jaw, in a lad aged six years. He brought it before the medical society of London as a new operation for the relief of severe ectropion. The lower eyelid showed the granular surface of the palpebral conjunctiva for an extent of three-eighths of an inch from above downwards. The edges of the tarsal cartilage were pared on the upper two-thirds of their extent, and after freeing the lower eyelid by an incision three-quarters of an inch long, made parallel to it, and a quarter of an inch below its free border, the eyelids were then sutured together. Nine months after the operation the sinus had healed up, but the contraction of the parts had considerably drawn down the upper eyelid. A subsequent operation was done for the relief of this symptom, the ultimate result being very satisfactory.

A Possible Danger Attending the Use of Pure Terebene.

Dr. Alfred Harvey thus writes in the *Brit. Med. Jour.:*

J. H., aged 56, a chronic asthmatic, suffered from the beginning of December with severe bronchitis, with profuse muco-purulent expectoration. On December 21st, he began to take pure terebene (ten drops on sugar, every four hours,) with great advantage, the expectoration diminishing to *nil*, and the dyspnœa being much relieved. After the treatment had been continued for three days, the patient was seized with intense pain in the region of the left kidney, shooting into the pelvis and down the left thigh, with blood in the urine, and severe strangury. Cessation of the terebene treatment, together with the use of poultices and the administration of opium internally, resulted in speedy relief, and left little doubt that the condition was one of intense renal congestion, caused by the terebene.

Effect of Iron on the Composition of Milk.

Dr. Mendes de Léon has made a number of researches and observations on the supposed effeot of taking iron on the composition of the milk secreted. He finds that milk always contains a minute quantity of iron, which differs in different species of animals, cow's milk, for example, being richer in iron than human milk. He gave various preparations of iron to a healthy multipara and analyzed the milk, but was unable to detect any increase in the iron it contained; so that it would appear that iron given to the mother does not act on the child by passing into its system, but that it may act by improving the general condition of the mother, and thus causing her to secrete better milk.

Torsion of an Incisor Tooth.

Mr. Smale mentions in the *British Journal of Dental Science* the case of a boy aged eight who had the right upper central incisor twisted so that the mesial surface presented towards the lip. The tooth was grasped firmly by a pair of straight-bladed forceps and twisted into a good position, care being taken to press the tooth firmly into the

socket during the operation. It was tied to the surrounding teeth with silk twist in order that it might not return to its old position. A week afterwards it was quite firm, the tooth could be tapped, and he could distinguish between hot and cold applications. There was no discoloration, and the gum was quite healthy. Torsion may be used freely before the patient arrives at the age of twelve years, and should be always done at one operation. It is only applicable to the incisors.

Fainting and Syncope.

The common practice of raising fainting persons to a sitting or upright position is often sufficient to destroy the spark of life which remains. The death of an eminent English statesman a short time ago gave opportunity to the coroner for emphasizing this fact, and of pointing out how much more reasonable and sound it is to keep such persons in the prone position while restoratives and local means are adopted to enable them, if possible, to regain consciousness. Though inquiring into the cause of the appearance of the "shadow feared by man," the coroner is not unmindful that its advent is often preventable, and a due regard to the welfare of the living prompts him to give sage admonition as the result of his own experience of some frequent causes of death.

Gunshot Wounds of the Abdomen.

At the Société de Chirurgie of Paris, M. Trelat spoke on gunshot wound of the abdomen. A child who had received a wound from a revolver in the abdomen succumbed, and the autopsy showed that the death was due neither to peritonitis nor to perforation, but to intestinal occlusion produced by narrowing of the intestine consequent on partial resection of the canal. M. le Dentu said that he had seen several cases of abdominal wounds with perforation of the intestine which succumbed to peritonitis in from four to five days. M. Tillaux said that wounds of the small intestine were not necessarily fatal, and that spontaneous cure is not impossible. He considered that laparotomy was very hazardous, and should be reserved for extreme cases.

Pyæmia After Extraction of a Tooth.

Dr. Zawadski mentions in a Polish journal a case where the extraction of a lower wisdom tooth in a man, aged forty-six, by a "feldsher," was followed by a fatal result. The day after the operation the soft parts in the neighborhood began to swell; then followed severe headache, a rigor, and fever, death occurring on the nineteenth day. At the necropsy, purulent inflammation of the dura mater of the base on the left side was found, and purulent thrombi in the cavernous and superior petrosal sinuses. The soft parts near the angle of the lower jaw were infiltrated with pus, and there were broken-down thrombi in the neighboring veins; also metastatic abscesses in the lungs and spleen.

The Treatment of Goitre.

The treatment of goitre is very varied, and the results have been frequently disappointing. Women are attacked so much oftener then men that the deformity is much more felt. A Dr. Dugeut, says the *Med. Press*, has treated for many years, with almost invariable success, the unsightly tumor by injections of tincture of iodine of the ordinary strength. The syringe of Pravaz was the instrument used, and the first injection was made in the part the most resisting and fleshy. Frequently one injection sufficed, but more frequently it was necessary to repeat it several times at an interval of eight days. The quantity used each time was from a half to a full syringe. The injection was followed in most cases by very slight reaction, which did not last more than two days.

The Treatment of Diabetes Mellitus.

Before an English medical society, Dr. Collins read a paper on this subject. After referring to the manner in which the carbohydrates reached the circulation, he defined the part played by the saccharine and amylaceous principles of food; and how in diabetes mellitus there was a want of power to assimilate and make use of the carbo-hydrate group. The clinical features and pathology of diabetes led up to its treatment. Considerable stress was laid on the exclusion of all starchy and saccharine principles of food. Of medicinal agents, opium alone was of any value; alkalies, as salicylate of soda, etc., being partially useless.

Entozoa and Pernicious Anæmia.

Dr. G. Reyher, writing on the etiology of pernicious anæmia, points out that, as in a large number of these cases, a Bothriocephalus latus has been diagnosed and expelled by means of male fern, the patients subsequently recovering; and as the anæmia of

miners is now known to be due to the Anchylostomum duodenale, it is possible that all cases are due to entozoa of one kind or another, and that, therefore, diligent search should always be made in the fæces for the ova of tæniæ, etc. The treatment will, in cases of successful search, be obvious.

Adenoid Bronchocele.

Mr. Vincent Jackson showed a girl, aged 14, to an English medical society, who had been sent to him on account of alarming symptoms occasioned by a very large adenoid bronchocele. Asphyxia seeming imminent, Mr. Jackson completely divided the very broad isthmus, and removed a small portion. The operation was followed by the complete relief of the symptoms, and by diminution of the size of the tumor to the extent of one inch.

Iodoform Pencils.

Dr. Oscar V. Petersen, of St. Petersburg, recommends (*Vratch*, No. 51, 1886, p. 908), in the treatment of syphilis, pencils made of 50 or 70 per cent. of iodoform, together with glycerine and gum arabic, and enclosed in a wooden holder. In the case of a chancroid ulcer, the pencil need only be applied to its surface, which then becomes coated with a more or less thick layer of iodoform. The chief advantage of the method is, that the patient remains absolutely free from an unpleasant and tell-tale odor.

Papine for Children.

From the *New York Medical Jour.* we learn that Dr. Wm. J. Crittenden, of Unionville, Va., recommends papine in cases in which the patient, on account of idiosyncrasy, cannot take opium or any of its preparations. It can be given in doses of thirty minims to a drachm.

Vomiting in Young Infants.

Dr. A. A. Smith, of New York (*N. W. Lancet*), recommends one grain of calomel to one ounce of lime water; to this add one pint of pure water, and give a teaspoonful of the mixture every ten minutes.

—The report of the Charité Hospital in Berlin shows that 17,010 patients were admitted during the year 1886, to which number must be added 1253 infants born alive, also 79 stillborn. The total deaths amounted to 1904. The cases cured numbered 14,892.

Correspondence.

Gunshot Wound of Brain—Recovery.

Eds. Med. and Surg. Reporter:

I have, to me and to many more of our community, an interesting case that I would like to report through your journal.

I was called and took with me Dr. W. C. Niver, of this place to see Martha B., aged nine years, who lives near Brockport, Elk county, Pa., and who had been accidentally shot by her older brother a few hours since. The young man was cleaning his revolver, when it went off, the bullet taking effect in the upper and central portion of the right parietal bone, going through and down into the brain to the depth of 2 or 2½ inches, with the following symptoms:

October 24. Found her lying on her right side in semi-comatose condition, with brain matter oozing from the wound. Pupil contracted to pin-hole. Pulse 60, temperature natural, respiration slow; but every few minutes had vomited, and was still making the effort. On probing the wound we found that the bullet had taken a downward and slightly posterior direction. We concluded that the bullet was beyond our reach, and contented ourselves by using means to allay the irritation and keep down inflammation, with the history as follows:

October 25. Semi-comatose; complains of pain in the head; vomiting; frequent urination; bowels constipated; pupil much dilated; pulse 65; temperature natural; restless.

October 26. Dozing a good deal; vomiting has ceased; irritation of bladder ceased; pulse, 65; temperature natural; respiration slow but easy; bowels constipated, but has eaten a little. There is now paralysis of motion of right side of face and left side of body.

October 27. Symptoms much the same, except bowels moved; resting pretty well.

October 28. Just the same in general symptoms, but has convulsions every twenty or thirty minutes all the day.

October 29. Convulsions ceased; can move left hand a little; pulse, 90; temperature natural; respiration natural; resting well.

From this time on she has gradually improved in every respect. At this date the girl is up and about the house, and complains of nothing, and has complete use of all her senses. The wound is yet discharging. Morphia and potass. bromid. were all the drugs used, with cold water.

M. M. Rankin, M. D.

Brockwayville, Pa.

Union by First Intention after Amputation without Asepsis.

EDS. MED. AND SURG. REPORTER:

The following case of union by first intention following an amputation may be of interest to the readers of the REPORTER. There was no attempt made during the operation or subsequent to it to secure an aseptic condition in any respect:

January 14, Alexis Hawkins, a boy about fourteen years old, came into my office and informed me that he had "shot his finger off."

Upon examination of the wound, I found the missile—a bullet from a 32-calibre revolver—had passed through the second joint of index finger of right hand, shattering the bones and leaving the muscles and tendons hanging in shreds. I amputated the finger half an inch below carpo-phalangeal joint; and having read in the REPORTER of the successful application of fluid extract of calendula, I concluded to give it a trial. With a camel's hair brush I thoroughly painted the inside of the flaps with a glycerole of calendula, brought them together, closed the wound with sutures of ordinary white silk. I then made a paste of iodoform and the glycerole, with which I saturated absorbent cotton and applied it to the wound, retaining it by bandage. I gave the boy's mother a bottle of the calendula, and directed her to keep the cotton wet with it.

Saw him on the 13th; he had had no rise of temperature or pain. I visited him every two or three days until the 19th, when I removed the dressing. There was no odor; not a drop of pus. There was no suppuration in the track of the sutures. The flaps were apparently firmly united. There was no swelling, very little tenderness, and during the entire time he had not suffered pain. There was no puffiness of the stump—no doughy feel to it.

I saw the case again February 1, and the wound was apparently well.

This is the first case of amputation that I ever saw unite without suppuration, without pain, and without swelling or soreness.

I do not know but the calendula would have been equally successful without the iodoform. Will try it alone the first opportunity. J. B. HATTON, M. D.

Red Oak, Ia.

—A Professorship of Hygiene has recently been created at Breslau, to which Professor Flügge, of Göttingen, has been appointed, where he is Director of the Institute of Chemistry and Hygiene.

NEWS AND MISCELLANY.

How the Reporter Saved a Dying Consumptive.

"You may abuse newspaper men all you please," said a robust chap in the smoking-room of a sleeping-car, "but I want to tell you that I have a weakness for reporters. A reporter once saved my life." "How?" "Well, three years ago I thought I was dying with consumption. My friends thought so, too. It appeared to be a clear case. One day a reporter bustled into my room, took out his pencil and note-book, and began business, without any unnecessary delay. 'Mr. Johnson,' said he, 'I understand that you are dying with consumption. Will you please give me a history of your life?' Well, gentlemen, but for that reporter I should not now be alive. I summoned all my remaining strength, threw the reporter down stairs, slid down the banister and jumped on him before he could get up, pounded him into a black swelling, and then threw him into the street. An hour later I heard he was likely to die from his injuries, and so I took the first train for the West, going clear up into the mountains and roughing it like a prospector. Now, look at me!" "Did the reporter die?" "Not a bit of it. He's now the editor-in-chief of a paper in Cincinnati."

Angry at His Own Salvation.

"Talking about druggists' mistakes," said a man who runs a pill factory in Chicago, "I'll tell you a funny mistake I made about three years ago. A young German came into the store and said he wanted fifty cents' worth of arsenic to feed to some rats. I sold him what I supposed was the poison, and would have thought no more of the sale if the fellow had not come round the next day and berated me for selling him quinine for arsenic. I learned later that the German, who had become despondent over some money matters, bought the 'arsenic' with the intention of committing suicide. He took the quinine to his lodgings, put on his grave-clothes, shaved himself with a dull razor, and then lay down upon the bed with a teaspoonful of the alkaloid in his stomach. When he woke up the next morning and found himself alive, he came to the store and relieved himself of his bile. Three weeks later he got a good job in a down-town clothing house, and is now earning a good salary."

Drugging Criminals to Further Justice.

A cable despatch from Paris to the *New York Herald* says that this study has become a passion among medical men, who say it may greatly help legal procedure, inasmuch as by sending criminals to sleep and dragging their secret from them while under hypnotic influence there would be little fear of judges condemning the innocent for the guilty. A theft in the hospital was found out in this way by Dr. Marie, for many years Dr. Charcot's assistant. The subject refused at first to tell where the stolen object was concealed. After a little diplomacy, however, on the part of the young doctor, who told the sleeping girl he was the young man from whom the card-case had been taken and not to fear telling him where it was, she gave the detailed account of having stolen it, and told where the card-case was to be found. Dr. Marie immediately went to the spot indicated, where, sure enough, the stolen article was found.

What Doctors Sometimes Endure.

A rather ludicrous incident happened to a physician at New Kingston the other day. The physician, Dr. Gibson, who has lately moved to that place, was called upon to see a patient—an aged woman, but of strong muscular build and energy. He thought, after some little conversation, that she suffered with rheumatism, and was about to place a seat for her near the light in a warmer room, where she had followed him with her husband, when, without a word of warning, she struck Dr. Gibson in the neck, and with so violent a blow that for a moment he was afraid he would lose consciousness. The unfortunate woman's mind was unbalanced, and for some time past she has labored under the hallucination that every physician who has been brought to see her was a horse doctor, who mistook her for an animal of that genus, and wished to give her that kind of medicine.

Thought He Had 'Em Again.

Two men sat beside each other in the parquet of the Chicago Opera House one night recently, and watched the presentation of "The Rat-Catcher." When the curtain fell on the flight of all the rats in Hamelin, one of the men turned to the other and said: "Pretty well done, eh?" "What was well done?" asked the other. "Why the rats. I say it was well done." "I didn't see any rats," replied the wag. "Didn't see a half a thousand of them going into the river and crawling over the bridge?" "Naw." "Why, you must have seen them. They were as plain as the nose on your face." "There wasn't a rat on the stage." "Sure about that?" "Would bet money on it." The man who had started the conversation clasped his hands to his head, looked appealingly to the solemn man by his side, and then grabbed his hat and rushed out of the theatre.

When the Supreme Judges Had Wine.

Many years ago, when Mr. Quincy, the junior, was on a visit to Washington, Mr. Justice Story entertained him with an account of the social life of himself and his associates on the Supreme Bench. "We usually dine together," he said, "at 6 o'clock, very quietly and simply. We have wine only when it rains." And after pausing a little on this statement, he added, with judicial gravity: "But sometimes the Chief Justice will say before we rise from table, 'Mr. Story, look out of the window and see whether it is raining,' and when I report that the weather appears to be fair, he will say, 'So much the better. Our jurisdiction is so vast that, according to the doctrine of chances, if the weather is fair here it must be raining in some other part of the country; therefore we will have a little wine to-day."

The Diseases of Wild Animals in Confinement.

Dr. H. C. Chapman says that nine-tenths of wild animals in confinement are subject to heart disease, although all animals have their peculiarities. The elephants are heir to many diseases, but the most common and fatal is rheumatism. Monkeys and baboons generally die from bronchial affections and heart disease; felines, such as lions, tigers, leopards, etc., from dysentery and heart disease; deer, antelopes, etc., suffer most from dysentery and heart disease; while the canine tribe, such as wolves, dingoes, foxes, etc., don't seem to be subject to any disease except pure cussedness. The only thing to be feared in the wolf tribe is too much sociability. It is unsafe to keep more than a pair together, otherwise they would eat each other.

Acrobats and Science.

M. Guyot-Daubès, in a work entitled *Hommes-Phenomènes*, enumerates the services rendered to science by the class of acrobats known as sword-swallowers. Owing to the amiability of an acrobat, Stevens, in 1776, was able to study the human gastric

juice. For this purpose, he placed small quantities of meat in metallic tubes pierced with holes, which the acrobat swallowed and brought up again when directed. Sword-swallowers have demonstrated how instruments for facilitating swallowing must be adapted. Fauche's tube is based on their information; also the construction of œsophageal catheters, for injections into the stomach, and the invention for illuminating the stomach with the electric light. In a word, acrobats are unknown benefactors to science.

Superstition against Doctors.

A lay contemporary tells us that a case of alleged witchcraft has recently come to light in Reading. The supposed witch is a woman who has been in ill health for years, and the victim the wife of a shoemaker. She has been afflicted for nine weeks past. Her left leg first doubled up, and then swelled to thrice its normal size. Her skin began to darken, and in a few days she was black as coal from head to foot. For seven weeks she suffered excruciating torture, screaming day and night and taking no food whatever. Several days ago she began to shed the black coat, and is now improving.

The doctors pronounce it a case of inflammatory rheumatism, with other complications; but the superstitious neighbors declare it to be the work of a witch.

To Roast a Small Roast Well.

Small families often complain that they cannot have good roast beef because they are obliged to buy such small pieces, and it comes upon the table dry and overdone. To prevent this, the smaller the piece to be roasted the higher the temperature to which its surface should be exposed. It should be crusted or browned as quickly as possible, so that the juices within shall be held there under high pressure, and only be allowed to escape by bursts and sputters, rather than by steady evaporation. No more fuel need be consumed, since it would take a shorter time to cook.

Edison's Lungs Diseased.

It is reported that Thomas A. Edison, the electrician, is not likely ever to return from Florida, where he has gone for his health. He had a severe attack of pleurisy last December, and it left his lungs hopelessly diseased. His recovery is deemed impossible. His health was never robust, and now he is helpless. He insisted on carrying along his uncompleted inventions, which are more numerous and wonderful than those which have become of practical value, and at Fort Meyers he will try to continue his experiments. He is accompanied by an expert and clerical staff.

Why Roscoe Conkling Wears a Curl.

An Auburn lady tells this about Roscoe Conkling: "One day when Roscoe was visiting my father's family, the horse and sulky were brought up to the door, and my father was just getting ready to start out for a ride among his patients. Young Roscoe thought he would get some life out of the old horse, took a pin and stuck it in his haunches, when the usually staid animal suddenly gave a kick and hit Roscoe a severe blow on his forehead, cutting a gash that to this day leaves a scar on the brow. And this is why the ex-Senator permits a little curl to drop over it."

Disturbing the Dead's Sacred Rest.

The other day at Washington, D. C., a lady believing her deceased husband had not been allowed by resurrectionists to rest in peace, insisted upon having the grave uncovered and the coffin lid opened. Her husband's corpse had not been stolen. She beheld a petrified image horribly staring at her. Then she repented her act, and fell into a sickness that may prove fatal. Could the stony lips of her husband have spoken, he might have moaned, as did the spectre of Samuel to Saul: "Why did you disquiet me to bring me up?"

The Girard House Medicine Cup.

In the Girard House, a large hotel of this city, leading to the porters' room, there is a white marble ice-water fountain, with a silver cup dangling from a chain. So many people have been taking pills, cod-liver oil, cough mixtures, and other decoctions with the help of the silver cup, that the cup got to taste like all the medicines that were mixed in it, and it smelt like a drug store. Recently another silver cup was chained to the fountain, and over the old cup hung a sign which read, "This is the medicine cup."

Dental Surgery on the Continent.

According to the *Independent Practitioner*, in Austria and Hungary there were until lately no dentists, medical men alone being allowed to practice dentistry. Before the year 1876, in order to practice dentistry in

Holland, it was necessary to hold the diploma of medicine, surgery, and midwifery. The law has now been amended; a special course of study and special examinations having been provided for, as in Germany, Russia, and Switzerland.

An Appeal to Unwatched Honesty.

A gentleman stepped into the Wright House in Parkesburg the other day, and, having time before the train was due, threw his overcoat in the window, and asked a young man sitting close by to keep an eye on it till he would go up and get some supper. "Certainly," was the reply. When he came back, the young man had changed positions, and attached to the coat was a card on which was written, "Dont Touch It; This Man Has Just Had the Small-pox."

A Commendable Act in a Suicide.

The *San Francisco Alta* says:

"Occasionally a fellow gets down to facts. Now there was Dr. A., of N———, who committed suicide, leaving behind a note in which he said: 'I die without malice to any one. I go to hell.' It is so seldom a man leaves his future address under such circumstances."

Afraid Moles Will Eat His Body.

West Chester possesses a character. He is afraid of moles attacking his body after interment. He owns a lot of land in Greenmount Cemetery, and occasionally he goes to that lot and deposits broken glass on the land, hoping in this way to keep away the moles after he has been laid away to rest.

Mortality of Medical Men at Matanzas.

The Havana journal, *La Enciclopedia*, states that during the last three years no less than eight medical practitioners have died at Matanzas, which is a port in the northern part of the island of Cuba, the population which is only about 35,000.

Items.

—A German inquirer has, it is stated, taken four heads of hair of equal weight, and then proceeded to count the individual hairs. One (red) was found to contain 90,000 hairs; another (black), 108,000; a third (brown), had 109,000; and the fourth (blonde), 140,000.

—Professor Virchow, who has long represented one of the divisions of Berlin in the Reichstag, is to be opposed at the general election now approaching by Field-Marshal Count von Moltke—a battle of giants, in which the cause of Parliamentary government is championed by the pathologist.

—Dr. Mariano Semmola, Professor of Experimental Therapeutics in the University of Naples, has consented to deliver one of the "General Addresses" before the International Medical Congress at Washington. He has chosen for his subject "Bacteriology and Its Clinical Therapeutics."

—A prize of fifty thousand francs is offered by the French Minister of Education for a discovery rendering electricity economically applicable in the shape of heat, light, chemical action, mechanical power, transmission of messages, or treatment of disease. A committee, with M. Bertrand, of the Academy of Sciences, as its chairman, will adjudicate.

—Herr von Bergmann, Professor of Surgery in the University of Berlin, has just declined an invitation to be chief surgeon to the Willig's Hospital in St. Petersburg. This institution, a palatial structure, and fitted with all imaginable appliances owes its origin to the private physician of Alexander I., who devoted his fortune to its establishment.

—The Sanitary Commission at Naples has determined, upon the recommendation of Semmola, to erect a laboratory for the practice of Pasteur's method of inoculation. The circular which announces its erection, urges the need of further experimentation with this method, to enable an accurate estimate to be made of its worth.

—He (just been refused): "Then life has no further charm; I shall kill myself."

She: "By poison?"

He: "Probably."

She: "Well, you'll excuse my mentioning it, but brother Jack has just opened a chemist's shop, you know, and would you mind buying the poison of him? It would encourage poor Jack, and prove your devotion to me." (He still lives.)

—William H. Crane, the comedian, tells this new story of his boy: "His mother asked him the other day whom he had been playing with, and he answered that he had been playing with old Jule Seligman's little boy. 'Hush, my dear,' cried his mother, 'that's not the way to speak of Mr. Seligman. His name is Julius, not Jule.' 'Then,' replied the precocious child, 'I suppose that my papa's name is Bilious?'"

Pallas Syringe."

[From the *London Medical Record.*]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten aces. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,
CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of recitations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

—LANDRETH'S SEEDS ARE THE BEST—
NORTH, SOUTH, EAST, OR WEST!

Everything of the best. SEEDS and IMPLEMENTS for Farm, Garden, or Country-Seat. Illustrated and Descriptive Catalogues Free upon application. Over 1500 acres under cultivation growing LANDRETH'S Garden Seeds. Founded 1784.

A CONTRIBUTION TO THE STUDY OF THE OPERATION OF SHORTENING THE ROUND LIGAMENTS—ALEXANDER'S OPERATION.*

BY THOMAS A. ASHBY, M. D.,

Professor of Gynecology in the Baltimore Polyclinic and Post-Graduate Medical School, etc.

There can be little doubt of the fact that the uterus is the most movable organ in the female body. It changes its position in the pelvis with each inspiration and expiration, rising and falling with rhythmic precision. Its axis in the pelvis is constantly influenced by the contents of the bladder and rectum, being displaced forwards or backwards by the fullness or emptiness of these organs. This latitude of motion has been wisely provided for by the character of its anatomical arrangements and supports. At once restrain the uterus from assuming its various normal relations to other pelvic organs and viscera, and the consequences become apparent. The extent of motion allowed the uterus is a varying quantity within certain limits. The exact position of the uterus in health is a point which cannot be established, since with every woman the relation of this organ to other organs is as variable as the shape of the nose or the expression of the features. The uterus is found turned or flexed at different angles in many individuals without giving rise to the least inconvenience, whilst in others the slightest deviation of the organ from its normal axis in the pelvis is accompanied by distressing symptoms.

The uterus is supported in the pelvis by tissues which perform the function of bumpers rather than the support of strong ligaments, hence its support is to be measured rather by the tonicity of the tunics which invest it than by connecting fibres which restrain it like so many stays or braces. The body of the uterus is invested by the peritoneal membrane, which, though closely adherent to its anterior and posterior surfaces, is given off in folds on its lateral borders to form the so-called broad ligaments. As the peritoneum is reflected from the anterior and posterior surfaces of the uterus, it turns up over the bladder in front and rectum behind to form the so-called utero-vesical and utero-sacral ligaments. In addition to these so-called ligaments two rounded cords, made up of areolar tissue, vessels and nerves, besides a dense bundle of fibrous and muscular tissue, are given off from the sides of the uterus, near the fundus, and curving around between the folds of the broad ligaments, pass through the internal abdominal ring along the inguinal canal, and, as they emerge from the external abdominal ring, are lost in the tissues of the labia majora. These cords are known as the round ligaments. They present the appearance of a true ligament, and may be so regarded. These ligaments are between four and five inches in length, and as they run in a tortuous direction through the folds of the broad ligaments and curve round the sides of the bladder, they hold the fundus of the uterus nearer to the symphysis than their length would indicate. It is believed by some anatomists that the round ligaments have the peculiar function

* Read before the Baltimore Academy of Medicine, February 1, 1887.

of drawing the uterus towards the pubis. They are also believed to aid in fixing the uterus in its proper axis in the pelvis. In addition to the supports mentioned, the uterus is held in its position in the pelvis by the walls of the vagina, which surround the cervix and embrace it as a keystone at the arch of the vaginal roof. The vagina in turn is maintained in its long diameter by the tonicity of its muscular and cellular coats, and by its attachments to the bladder in front and rectal wall behind. When all of these tissues are in a condition of tonicity, they conjointly support the uterus and pelvic organs. When greatly relaxed from any cause they allow the uterus to sag down in the pelvis and to draw down its natural supports. Thus prolapse of the uterus necessarily drags down its peritoneal investment and the round ligaments, depresses the vaginal arch at the cervix, and draws in the anterior and posterior vaginal wall, first at the internal end of the vaginal tube, and next along its entire extent. This process of descent may be reversed in those cases of rectocele or vesicocele where the uterine support is weakened at the external end of the vaginal tube. When the tissues which make up the pelvic roof retain their tonicity, even in the abscence of vaginal support, the descent of the uterus is resisted and the organ can only be dragged down through the vulva by overcoming this resistance. When the uterus is strongly seized with vulsellum forceps and drawn down in the vagina, we have this condition. The broad ligaments are put on the stretch; the bladder is drawn down with the uterus, owing to the intimate connection between the two; the rectum is not disturbed, owing to the loose attachment of its subperitoneal connective tissue to the vagina. If the broad ligaments now be severed, complete prolapse of the uterus is secured. The round ligaments are the last tissues put on the stretch. From this history of uterine prolapsus here described, it would seem that the round ligaments play a very insignificant part in supporting the uterus, whilst the broad ligaments and utero-vesical and utero-sacral folds of the peritoneum materially add to the support of the organ.

When we come to study the causes of version and flexion of the uterus, we find the same deviations from the normal axis with variations within health according to the individual point.

Anteversion is regarded by anatomists as the normal position of the uterus. In childhood, and in the woman who has not borne children, the uterus is almost invariably turned forwards. The reverse position, retroversion, is the most frequent form of displacement. Uterine flexions are almost invariably due to faulty nutrition of the uterine muscles, but they may result from overpressure from tumors, or from intestines forced down into the pelvis by tight lacing. Flexions may occur in the cervix or in the body. The first named variety is referable to undue length of development, the elongated cervix being bent upon itself by mechanical pressure. Flexions of the body of the uterus must be attributed to the weakened supports of the uterine walls, which yield under super-imposed weight, either connected with the uterus itself, or external to the organ. The broad ligaments undoubtedly exercise an influence in the prevention of versions and flexions, but where these supports are relaxed or overstretched by constant strain exercised upon them, their restraining influence is overcome. The utero-sacral and utero-vesical ligaments are simply folds of peritoneal tissue, which exercise but partial resistance against version and flexion. The function of these ligaments seems to be to aid in the suspension of the uterus in the pelvic canal. The round ligaments coming off from the fundus and passing forwards into the inguinal canal undoubtedly exercise a strong influence in preventing posterior displacement of the uterus. Their course around the bladder is somewhat tortuous; this may allow a certain amount of lengthening, estimated at from two to three inches, before they are made taut by the posterior displacement of the uterus. The round ligaments exercise but little if any influence in preventing prolapse of the uterus. Savage has shown that after all the other supports to the uterus are severed, they are the last made taut by procidentia. In view of the fact that the round ligaments have the power of drawing the fundus of the uterus forwards, the advantage of shortening their length in cases of posterior uterine displacement is now an established fact. As far back as 1840, Alquié, a French surgeon, proposed the operation of shortening the round ligaments, but he failed to demonstrate the value of this procedure upon the human female. It was not until 1881 that the operation was performed upon a woman. On December 14, of that year, Dr. Wm. Alexander, of Liverpool, operated successfully on a case of prolapsus uteri, by drawing out and shortening these ligaments. Whilst not the originator of the operation, to Dr. Alexander belongs, therefore, the credit of its first performance. The opera-

tion very properly now bears his name. Since Dr. Alexander first operated, he has been an earnest advocate of its advantages, and he has performed the operation more frequently than any other surgeon, with results of a very satisfactory character. The Alexander operation has now been performed over two hundred times in this country and in Europe, by a number of different surgeons, with varying degrees of success, and with corresponding difference of opinion as to its value. It is a procedure which is still under trial and criticism. It is incumbent upon those who have had an experience to record the same. It is by a study and comparison of the various steps of the procedure and a report of results that its advantages and disadvantages will become apparent. Having performed this operation in June last, I shall present a report of the case, and then discuss a few of the steps of the procedure.

Mrs. ———, aged fifty years, a widow, had suffered for a number of years with uterine disease. For four or five years previous to the date of operation she was almost a confirmed invalid, her life being a burden to herself, and, as she imagined, to her friends. During this time she had been under the treatment of several well-known and skillful gynecologists, all of whom had recognized her true condition, but had afforded her only very temporary relief. Becoming discouraged, she wandered from one physician's office to another until local and general medication had been faithfully tried. She still remained the victim of morbid anxiety and severe suffering. Coming under my treatment in the early part of last year, I succeeded, as did my predecessors, in obtaining her consent to a vaginal examination. She was flooding profusely at the time, so that I administered ergot and desisted from an exploration until hemorrhage had ceased. I learned from her history that she was subject to intense menorrhagia, which invariably left her weak and prostrated from the loss of blood. In person, she was plump and well nourished, but her skin and conjunctivæ were extremely pale and anæmic. She was extremely nervous and dejected in spirits, and longed for death as the surest way of escape from mental and physical suffering. She manifested no hope of relief, but expressed a great willingness to undergo any plan of treatment that would give her some benefit. A few days subsequent to the time she first came under my care, I succeeded in making a physical exploration, and I found that her condition coincided with the history related by her, which she had obtained from other physicians. Her uterus occupied a low position in the pelvis; the body of the organ was large, flabby, and relaxed; the fundus rested against the sacrum; below the promontory, on its posterior wall, were several fibroid tumors, interstitial, varying from the size of a walnut to a medium-sized apple. These growths were irregular in shape and outline, and presented a hard nodular feeling to the touch. The uterine cavity was tortuous, roomy, and admitted the sound to the depth of $3\frac{1}{2}$ inches. The uterus was perfectly movable, and could be easily elevated into its normal axis, but the moment support was withdrawn it tumbled back into its acquired position. The pressure made against the rectum by the displaced organ was the chief source of discomfort. The patient suffered from a distressing flatulent dyspepsia and from constipation. The pressure of the uterus prevented an escape of flatus by the rectum, and also occasioned such suffering that defecation was performed with the utmost difficulty. Enemas or laxatives were invariably required to secure a passage from her bowels. So long as the uterus was maintained in its normal position these symptoms were relieved. It was quite evident that the mechanical pressure of the displaced organ was the prime cause of both physical and mental distress, and also contributed in a measure to the profuse loss of blood during menstruation. The congestion of the menstrual epoch occasioned most violent cramps, nausea, and other disturbances, so that the recumbent posture was required during all of this time.

It was my opinion that any mechanical contrivance which would hold the uterus in position would relieve the pain and distress consequent upon displacement.

I determined at once to use a properly fitting pessary, but was informed by my patient that she was unable to wear pessaries—that she had worn a number without relief. I insisted upon further trial, and during the next two months I employed every mechanical device which I could obtain, with total failure.

I then suggested the Alexander operation, and explained the advantages of the procedure in her case. She readily consented, and in fact urged me to undertake the operation; she was more anxious than I was to test its value. Whilst I believed in the *rationale* of the method proposed, I had some misgiving as to the value of the method in her case, though it seemed to me that if her uterus could be drawn forwards and fixed, the ten-

dency to displacement backwards would be removed. At this juncture I was greatly aided by the experience, skill, and anatomical knowledge of my friend, Dr. Randolph Winslow, of this city. Dr. Winslow had performed this operation twice upon the living subject, and had also demonstrated upon the cadaver the fact that the uterus could be easily elevated into position by the round ligaments, and there be retained by traction upon them.

The operation was performed on the 8th day of June, with the assistance of Drs. R. Winslow, John E. Jay, and W. J. Chappell. After etherization an incision was made over the external abdominal rings and the superficial tissues were cut through until the external end of the round ligament came into sight. These were dissected out and the ligaments were gently drawn through the canal until some three inches of their length were external to the canal. As traction was made on these ligaments the uterus was observed to rise in its normal axis in the pelvis. A sound was inserted into the uterus to aid in its replacement. Having demonstrated a correct position of the uterus, the ligaments were attached to the line of incision by buried cat-gut sutures. Cat-gut threads were also placed along the floor of the wounds to act as drainage-tubes. The wounds were then closed. After closure of the wounds the sound was withdrawn from the uterus and a suitable pessary was introduced to aid in the support of the uterus until union had been secured. Primary union took place, with the exception of a slight discharge of pus along the tract of the cat-gut drainage threads. Within ten days the parts were entirely well. The patient had no trouble referable to the operation. Her temperature at no time was elevated above 100° F. After three weeks she was allowed to get out of bed, and from that time onward her improvement was continuous. On October 11 last, I received the enclosed letter from her, which explains her condition at that time.* I have seen her frequently since, and at this time of writing her health is so vastly improved that she is able to do any ordinary domestic duty. She has been relieved of the suffering incident to the mechanical pressure of the uterus on the rectum. She has had no show of blood since November last. It is believed that the menopause has been reached, and that her general health will improve from this time forward, as the great drain from loss of blood has been stopped. Before this operation was performed my patient could not walk across her room with comfort; she was on the verge of complete invalidism. She is now able to walk where she pleases, run up and down stairs with ease and agility. She has informed me that she has recently walked fourteen squares on shopping expeditions with comfort. Her mental and physical condition are so markedly improved that she seems unlike the same individual.

I have had no opportunity and no occasion to make a vaginal examination to verify the position of the uterus. Her sense of comfort and ease of motion are sufficient to prove to my mind that the uterus is now in proper position.

The inqury may be suggested, How long will it remain in its normal axis? My answer is, the remainder of her natural life. I see nothing in the present condition of the uterus to favor any other view. The organ has had its normal stays restored by shortening their redundant length. The menopause has been established, and the weight of the fibroid tumors will become less and less, now that this has been declared. As a matter of safe precaution and of increased comfort, a pessary will be worn for such a length of time as may seem judicious. It must be borne in mind that previous to the operation she was unable to wear a pessary with comfort.

Remarks.—The case here reported illustrates in a very satisfactory manner the advantages of the Alexander operation in certain forms of posterior uterine displacement. The uterus having been dragged from its normal axis by fibroid growths upon its posterior wall, had remained in this false position for some years. The nutrition of the organ had been impaired, its size increased, and a general relaxation of its muscular tone and ligamentous supports had been induced by these same growths. Whilst the organ could be readily restored to its position, it was found impossible to retain it *in situ* by any mechanical contrivance which had been employed. Pessaries gave intense distress, and could not be worn continuously for a longer period than one or two days at a time. They did but little good when employed. It was quite apparent that no form of mechanical support would be of service in this case, except a restoration of the normal ligamentous supports, which had become relaxed and

* Baltimore, October 10. 1886.

Dr. Ashby, Dear Sir:—I am happy to state that I have been very much benefited by the operation you performed on me last June. Previous to this I was a great sufferer, and could not sit up one hour with any degree of comfort. I can conscientiously say that I think the Alexander operation a great boon to those who suffer from displacement, and I would be more than willing to talk with any sufferer who is in doubt about it. Yours truly, Mrs. ————.

over-stretched by the continuous weight of the displaced organ. The results have demonstrated the correctness of these views. It is in just such a condition of posterior displacement as has been recorded in this case that we have the promise of satisfactory results from shortening of the round ligaments, and in which the advantages of this procedure are most conspicuous. I fail to see any striking advantage which will follow the shortening of the round ligaments in cases of procidentia uteri. The round ligaments can exercise but a feeble power in preventing the uterus from descending in the pelvic canal. It has been shown by careful demonstration that they are the last of the uterine supports to become taut in downward displacement. It is therefore doubtful whether shortening of these ligaments, in the absence of a restoration of the perineal support, would render any material or durable service. Nor do I believe the Alexander operation is destined to meet with success in cases of posterior displacement where adhesions have formed between the uterus and rectal tissues. In such cases more or less violence is required to sever the attachments before the uterus can be drawn into its axis by traction on the round ligaments. The advantage of the procedure under such circumstances seems of doubtful propriety. In those cases of posterior displacement where the uterus is easily replaced by sound or finger, where the muscular tone is simply impaired, and where pessaries are worn to no advantage, or with distress, the procedure under consideration is, in my judgment, not only admissible but positively indicated.

The Alexander operation has a limited field of usefulness, but when properly employed within the limits assigned to it, it is in my belief one of the most valuable procedures contributed to surgery within the last decade.

In this connection it is proper to discuss a few of the steps of the procedure. *First*, as regards the danger of the operation. As far as I have been able to collect statistics, the mortality has been less than two per cent. The operation is as nearly devoid of danger as any procedure can be, if it is properly performed. Among the cases reported, death was attributed to pyæmia in three cases, which resulted from want of care and cleanliness. Peritonitis is a source of danger, since it is possible to injure this membrane in drawing the ligaments through the canal. With ordinary care the peritoneum can be discovered and its injury avoided. *Second*, the difficulty of finding the ligaments has been referred to by several operators. In the case here reported no trouble, in this respect, was experienced. With proper care and a knowledge of the anatomical arrangements, the ligaments can be brought into view by cautious dissection. In a report of forty cases made in November, 1885, by Dr. Alexander, this difficulty was not experienced. Imlach, of Liverpool, has reported thirty-six cases, without difculty in finding the ligaments in a single case. As opposed to this experience, Mundé, of New York, was unable to find the ligaments in three cases out of six cases; he therefore claims that this is an element of uncertainty in the operation. The fact that the inability to find the ligaments has occurred in less than four per cent. of the cases reported is but a slight disparagement to the operation. Such a failure upon the part of the operator only necessitates the closure of the incision, and leaves the patient in the same condition she was in prior to the attempt.

I quite agree with Dr. Alexander in the statement that the operation is a delicate one, and quite different from ordinary procedures. The external end of the ligament lies imbedded in the tissues, and will be readily overlooked if not carefully dissected out. Its white sheen can be made to appear when gently drawn out of the ring. It then has the appearance and structure of a true ligament. The after-treatment of the operation should be conducted on strict surgical principles.

The following summary of conclusions is offered:

1. The round ligaments are designed to hold the uterus in its axis in the pelvis, and to draw the fundus of the organ towards the symphysis pubis. They have little if any sustaining power in preventing procidentia, except in extreme degrees of descent, where the organ has escaped external to the vulva.

Posterior displacement of the uterus can only take place when the round ligaments have been relaxed or stretched by prolonged tension.

2. Shortening the round ligaments is a practical method by which the uterus may be lifted into its normal axis, and be retained in position by a restoration of its normal supports,

3. This operation is admissible in all cases of posterior displacement where the uterus is not fixed by adhesions, but perfectly movable in the pelvis, and where other methods of support are not of service.

4. The operation can prove of little value in cases of procidentia, except when employed in conjunction with other methods in-

stituted to overcome this form of displacement.

5. The operation can be easily performed by one who is familiar with the anatomy of the parts. It is almost devoid of danger, if ordinary safeguards are employed.

6. In the class of cases to which it is limited, the benefits secured are striking and important.

THE CARE OF PATIENTS OF DOUBTFUL MENTAL STATE, AND THE PRIVATE TREATMENT OF THE INSANE.*

BY JOHN A. CLARK, ESQ.

The subject which I have selected for a short paper—"The Care of Patients of Doubtful Mental State, and the Private Treatment of the Insane"—is one deserving of more practical attention than it has yet received from the community.

There are a large number of nervous cases which appear to hover on the confines separating a morbid condition of mind from actual and pronounced insanity. In most of these cases it is a long time after the development of the early symptoms before the friends and family of the unfortunate patient can bring themselves to realize the gravity of the malady. What they require is some system of prevention which may arrest and ward off an impending derangement of the mental faculties. The patient requires rest and repose, the absence of all surroundings that can awaken or continue care and anxiety, and a judicious treatment both of the mind and of the physical health.

For persons in such a mental condition there should be sanitariums, or health resorts, where they would be subjected to such wise moral and physical discipline as would tend to promote their recovery. A separation from their family and friends frequently seems necessary to produce these results. Unfortunately, there seems to be but slight provision for such a class of cases.

Nothing can be more complex or unfathomable than the human mind. The moral treatment of the patient has more potency in promoting recovery than the administration of any drugs or medicines. The anxiety and solicitude of the family of the sufferer often appear to deprive them of the ability to deal with the exigencies of the case as well as comparative strangers might. Yet, when it fully appears that some important step should be taken, they feel the greatest repugnance to consigning the invalid to the walls of an insane asylum, especially when there is a reasonable doubt in their minds whether the person is really insane or not. It is for this very large class of cases that intermediate hospitals are required.

It is probably preferable that such hospitals should be maintained by and under the supervision of charitable corporations, under the wise management of competent and conscientious managers and trustees, although there can be no good reason why private individuals and specialists should not establish and maintain such retreats for those mentally affected.

Crowded asylums must certainly militate against the opportunities for recovery. The environments of the patient are bad. These massive structures, with their frowning walls and battlements, suggest to the unfortunate patient that he has been transferred from the freedom of his home to the desolate loneliness of the penitentiary. He is thrown in contact with the incurable and demented. Man is an imitative animal, whether his mind is clear and normal or diseased by hallucinations. There is certainly a contagion in being surrounded by persons indulging in every possible delusion. How much preferable, then, is the condition of the patient of doubtful mental state when sent for treatment to an institution which is exclusively devoted to the treatment of similar cases! Such a home now exists under the care of the Friends at Atlantic City, where pure air and cheerful surroundings have restored many persons suffering from nervous disorders to perfect health. Such institutions should be established either by the seaside or in the country, where the patients may have ample opportunity for exercise and recreation in the open air. They should only contain a limited number of patients, and should partake of the character rather of large families. There should be no gloom about such homes, no barriers or walls, no appearance of restraint—nothing, in fact, to impress gloom and melancholy upon the inmates, but all that is cheerful and bright, to allure them back, as it were, to mental health. There should be music and flowers, cheerful books, diverting amusements, together with a round of rational employments suited to the tastes of the different patients, which would tend to divert them from the melancholy suggestions of their own morbid thoughts. Above all, there should be intelligent management, and a recognition of the peculiarities and idiosyncrasies of each pa-

*Read at a joint meeting of the Philadelphia Neurological Society and the Philadelphia Medical Jurisprudence Society, January 24, 1887.

tient. The attendants should be persons of experience, cultivation, and refinement. They certainly would require the possession of some Christian fortitude to endure the vexatious exactions and irritating caprices of those they have in charge.

It has been said by a recent writer that it is difficult to draw the line between actual insanity and some acute nervous disorders, and therefore many cases have been consigned to an asylum for treatment which are entirely out of place in its associations or under its care. Acute cases of insanity and hybrid types of nervous disorder can be treated and cured without the unpleasant remembrance of an asylum, and without the injurious results which sometimes follow the injudicious incarceration of sensitive patients.

It is this consideration which brings us to the conviction that there should be such intermediate hospitals as I have described. They would not interfere in any measure with the asylums now in existence. The care of incurable patients and the treatment of those who have not yet reached that stage should certainly be separated. How much more essential is it, then, that those of a doubtful mental state, where insanity is not well established, should receive treatment in intermediate hospitals.

The question now arises whether there is anything in the lunacy law of the State of Pennsylvania which prevents the existence of such intermediate hospitals; and if there is, whether it would be wise to make some new enactments covering such cases. The Act of Assembly of May 8, 1883, entitled "An Act Relative to the Supervision and Control of Hospitals or Houses in which the Insane are placed for Treatment or Detention," has worked a great revolution in the supervision of this class of persons in the State of Pennsylvania.

This law has been supplemented by the Rules and Regulations of the Committee on Lunacy, which have been ordained by the Board of Public Charities and received the consent of the Chief Justice of the Supreme Court and the Attorney-General, according to the provisions of the act. This act, with the rules before referred to, provides for the granting of licenses for asylums, the admission of patients, and the supervision of such institutions. The personal liberty of the citizen is protected from the possibility of the detention of a sane person, and the management of the asylum is under such supervision as to prevent the abuses which have heretofore crept into some institutions.

This law is a highly commendable one, and the existence of the Committee on Lunacy is one that assures the public mind that institutions for the care and treatment of those deprived of reason are under proper supervision and control. Institutions or individuals complying with the requirements of this act are protected from all judgments against them for the detention of any person, unless the judge, after trial and verdict, shall "certify that there was proof to his satisfaction that the party charged acted with gross negligence or corruptly, or that he acted without reasonable or proper cause, or was actuated by motives other than the good of the person restrained."

No person shall be received as a patient for treatment or for detention, into any house or place where more than one insane person is detained, or into any house or place where one or more insane persons are detained for compensation, without a certificate signed by at least two physicians, agreeably to the provisions of the act and rules heretofore mentioned.

Certainly nothing in this act provides that persons suffering from nervous diseases may not be treated in the intermediate hospitals; but if doubtful cases are so treated, the very doubt implies that receiving such patients for treatment may be an infraction of this law. Persons may voluntarily place themselves in asylums, and may be detained for the time they shall specify by an agreement signed by them at the time of ther admission, but not exceeding seven days, and they may from time to time renew the authority to detain them for a time not exceeding seven days from such renewal. No agreement shall be deemed to authorize the detention unless signed in the presence of some adult person attending as a friend of the person detained, in the presence of and also by the person in charge of the house, or the medical attendant.

Thus it seems that if there were an intermediate asylum unlicensed by the Committee on Lunacy, in which there happened to be two doubtful cases of persons who should prove to be insane, the maintaining of such a house would be in violation of the law. No person could be received for treatment in such a house unless they had the certificate of two physicians, as required by the act and rules.

A literal construction of the act would seem to imperil any managers or other persons who would establish an intermediate hospital for doubtful cases without the same rigid compliance with the law which is required of those keeping insane asylums. It

is certainly worthy of the consideration of the medical profession and the Committee on Lunacy whether it would not be proper and expedient to secure some additional legislation to provide for hospitals of an intermediate character. One patient can be treated at home, or a physician could receive one such patient in his own house, but not more. It is doubtful whether it would not be ascertained on careful examination that any hospital provided for persons suffering from nervous disorders has at least two patients who are probably insane.

This subject does not appear to have received the consideration of the legislature when the act of 1883 was passed, and it is certainly worthy of discussion at the present time, which should be conducted in a calm and dispassionate manner, with the hope of a solution which shall be beneficial to patients suffering from nervous disorders which are likely to affect, if unrelieved, the soundness of the mind.

Medical Societies.

JOINT MEETING OF THE PHILADELPHIA NEUROLOGICAL SOCIETY AND PHILADELPHIA MEDICAL JURISPRUDENCE SOCIETY.

(*Continued from page* 272.)

"I may say in quasi reply to my distinguished friend on the opposite side of the room, that the person whom he followed to the gallows was convicted as properly under the laws as it is possible for a man to be convicted. The man may have been insane—such a thing is possible; but I believe that he was as properly convicted as a man can be under our very imperfect system of trial. We cannot look into the heart; we can only judge of the heart by the actions. Eighteen months ago there was something like an array in this room of the two professions against each other upon this point, which should not be. They should work together in all these subjects, and endeavor to pull in perfect harmony towards the desired end, and not be placed in antagonistic positions.

"A word as to what the treatment should be after a patient is received. In addressing the eminent gentlemen here to-night, and the chairman, who is himself an expert of the highest order of merit, I wish to make some suggestions which have occurred to me some time since. I believe that there is a large class of the insane who have no homicidal or suicidal tendencies, who could be allowed a greater measure of liberty than they have at present under our imperfect system. I wholly agree with the suggestions of my friend, Mr. Clark. There are, undoubtedly, a large number of men who may be of sound mind so far as the ordinary affairs of life are concerned, and who yet may be hovering on the border-line, and for whom residence in a hospital for the insane may be the worst possible treatment. If they could be separated from contact with associations which may be irritatingly exciting, and yet not be consigned to a hospital for the insane, but to some intermediate place of treatment, I believe that it would be a great gain. It is said, and I believe on the very best authority, that in order that there may be a good chance of a cure, the disease must be taken in charge very early. The statistics with which we were favored to-night show that the cases treated within from three to six months of the access stand a vastly better chance of recovery than those taken after the first year. If the suggestions of Mr. Clark were carried out, I believe that they would do much good. I go so far as to say that I believe that, even in the case of the incurable insane, much of the restraint could be removed. The only dangers to be guarded against are danger of the individual to himself and danger to others. We should protect society, and we should protect the party against his own acts; but we are not required to go beyond this.

"These are the thoughts tossing through my mind after hearing the excellent papers that have been read. I am not a partisan or extremist on either side. So far as the law is concerned, I am willing to admit that it is a very rough instrument, and only approximates—and that very imperfectly—to the dispensation of justice in human affairs. Medicine is a science—at least it is an art based upon scientific requirements—and has a much higher field than the law. I believe that all these great improvements come quite as much from the medical profession, if not more so, than from any other quarter; and I am looking for further advance from the eminent men in that profession."

Dr. E. N. Brush: "The objection made by Dr. Wood that there seems to be no provision by which a person dangerous to himself and to society can be placed in an asylum, except by the action of the friends, would seem to be met by the requirements of the lunacy statutes of the State of New York, which provide that a justice of the court may, upon com-

plaint, issue a warrant and summarily commit a person who is complained of by any one as being dangerous to himself or to others, upon taking proof as to his insanity. If his friends are not able to support him, the charges are collected from the county, otherwise his friends or estate must bear the expense.

"In regard to the accountability of physicians, I think that they are not anxious to shift any of the accountability which devolves upon them for careless or injudicious opinion; still the fact remains that there is nothing to prevent a lunatic discharged unrecovered from bringing action for damages, which, although unsuccessful, may put the physician to much expense in defending himself.

"I am happy to be so well supported in my plea for early treatment as I have been by Mr. Clark's paper. His suggestion for intermediate hospitals is in the line of early and prompt treatment.

"I see no reason, however, why the suggestions of Mr. Clark might not be applied to many of the asylums of this State. I am satisfied that there is no superintendent or physician connected with any asylum, if the cases were brought early, who would not be willing to place the patients in such a position that their recovery would be hastened and not retarded by unpleasant surroundings.

"At the hospital with which I have the honor of being connected, the Pennsylvania Hospital for the Insane, we every year treat a number of these incipient cases, who come and remain voluntarily, and who do not seem in any way disturbed by their surroundings; and we know of no legal objection to their remaining for indefinite periods, as long as no detention is exercised. As far as a patient's residence in an intermediate hospital is concerned, there must be some legal right to detain him there, in case he will not yield to the judgment of his friends or the physician, otherwise we are left in the same position as at present."

Dr. S. Weir Mitchell: "Eight or nine years ago, after returning from England, where I had been through many of the hospitals for convalescents attached to the great English hospitals in which patients of a doubtful mental state were placed, I went to the authorities of the Pennsylvania Hospital for the Insane and proposed, for myself and a lady of this city, to make a reasonably liberal gift for four years if they would start an institution of this kind. It was promptly rejected as not practicable. The offer was then made to the managers of the Friends' Asylum, but after consideration it was rejected. I am happy to learn that under the guidance of my friend, Dr. John C. Hall, better counsels have prevailed, and the first institution of this kind has been established near this city. I believe that there is a similar institution in New York State."

Dr. H. C. Wood: "I should like to say a word with reference to the remarks of my friend, Mr. Biddle, referring back to the old Taylor case. It seems impossible to get the legal mind to understand the position which I myself and, I believe, most of the medical gentlemen connected with that case took. I never said that under the laws of the State of Pennsylvania the criminal was not properly executed. I do believe that the laws of the State of Pennsylvania need alteration. The difficulty is that the legal gentleman who administers the law makes the law as it exists a part of himself, and then becomes a partisan of the law as it now exists. The legal profession come to believe that the law is perfect, and the moment any one dares to differ in that respect, that moment the elements of more or less partisan feeling make their appearance."

Dr. William L. Robinson: "There is one class of patients to which reference has not been made, and that is the criminal insane. I should like to know what disposition should be made of these people at the end of their sentence. If they are liberated, they are soon arrested for repeated crimes and returned to prison. We have already received this year at the penitentiary six insane people liberated in November last. The expense of the repeated trials of these people is great. There should be some method of disposing of them which would avoid this expense, and at the same time protect the community. Our asylums for the insane have not detained them when sent there. Will some of the chiefs of asylums present tell us of the influence of the criminal on other insane patients?"

Dr. John C. Hall: "I feel that I can speak somewhat experimentally, as the Friends' Asylum has tried this intermediate system of treatment, as Mr. Clark has termed it. Our house at Atlantic City has given good results. There are many cases that can be better treated in a small house than in the wards of a large hospital. There are many persons whose relatives would send them to such a house, and yet would not place them in a hospital, merely because of the prejudices which exist in reference to these institutions. I should be glad if some modification in the lunacy laws could be made to cover this particular point. This is, I think, a subject of vital importance."

Dr. Francis X. Dercum: "I think that the point raised by Dr. Wood has not been sufficiently dwelt upon—that is, in regard to the protection of the community against the insane who are not confined by their friends. A year ago I had an experience illustrating this very point. I was called in the middle of the night to a house in my neighborhood, where I found a woman in a state of acute mania. She had torn off all her clothing, and was engaged in a desperate struggle with her father and two sisters. The latter soon became terror-stricken. I alone was unable to control her, and we were obliged to call in assistance feom the street, and we had the unedifying spectacle of a strange man, a policeman, and a physician, in a struggle with a naked woman on the floor. The patient was finally quieted by the hypodermic use of sedatives. The next morning I called at the house with the object of arranging for her removal to an asylum. I was met with a prompt refusal. In my ignorance of the law I went to the police station and informed the sergeant of the facts of the case, and there the matter ended."

Dr. Charles K. Mills read a paper entitled

Suggestions as to Lunacy and Inebriate Laws.

DISCUSSION.

Dr. S. Weir Mitchell: "With reference to voluntary incarceration, I wish to say that I was one of the commission that framed the law of 1883. I made great efforts to have this period of one week changed. I desired that it should be made at the will of the person concerned, but limited to six months. I was, hower, unable to bring a majority of the commission to this view."

Dr. S. Preston Jones: "I have made some inquiry in reference to this law in Connecticut, but I do not find that it has been resorted to to any extent. At the Retreat at Hartford they have received only one patient in ten years, under its provisions. There is only one inebriate asylum in the State, and that is a private one. The law was amended two years ago, so as to permit a judge of probate to put the inebriate under the care of any reputable physician in the State. There is a law in this State providing for the care of the property of a drunkard, but it is rarely resorted to.

George W. Biddle, Esq.: "I wish to express my concurrence with Dr. Mitchell in regard to the desirability of extending the period for which a man may voluntarily commit himself. This is reasonable to the last degree. I should have gone a little further, and have said any time within one year, if the patient choose."

Dr. Charles K. Mills read a paper on "Confessions of the Insane," and related the case of a patient who confessed (about the same time that Wilson made his confession) to having murdered a man named Stahl, and to having thrown his mutilated body into Wissahickon Creek.

The next paper was entitled "Description of the Brain of John M. Wilson, Recently Hanged at Norristown, Pennsylvana," by Francis X. Dercum, M. D.

(*To be continued.*)

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated meeting February 9, 1887.

The President, J. Solis-Cohen, M. D., in the chair.

Dr. George W. Vogler read the report of

A Case of Suppurative Inflammation of the Liver in a Child Twelve Years of Age; Operation and Recovery.

M. C. S., a bright, precocious school-girl of rather delicate and frail build, dark-complexioned and tall, presented the following history:

On October 7, she first complained of intermittent pain immediately over the right hypochondriac region, corresponding to the right lobe of the liver, and at the same time began to favor the part by slightly bending forward and to the right side when standing or walking. She was still attending school, and kept up active exercise. There were, apparently, no other symptoms present—at least she complained of none. This state of things continued for about one week, the little patient continuing her school duties, although with much suffering and inconvenience. She now refrained from going down to recess with the other children. The pain became more severe, especially at night, producing great restlessness, and interfering with sleep. The stooped condition of the body was now permanent; walking was discontinued owing to pain; and some fever (at night particularly) also manifested itself, with marked impairment of appetite, coated tongue, thirst, cloudy urine, and constipation.

Both the mother and child, after several careful examinations of the part, found nothing to account for the trouble. In the meanwhile, a physician in attendance upon another member of the family was asked to look at the child. He examined her several times, but found nothing of note, and pro-

nounced the case as probably a strain, or one of cold, for which he ordered a plaster, and some citrate of magnesia for febrile disturbance. The child continued to grow worse daily, and the same physician ordered a fly-blister to the affected part. It may be mentioned just here that the pain never shifted, but was always confined immediately over the area corresponding to the right lobe of the liver. Flaxseed and onion poultices were ordered to be applied by the medical gentleman upon noticing later a slight swelling over the seat of pain. Upon November 12, five weeks after the commencement of her illness, I assumed charge of the case. I found her bedfast, greatly reduced in flesh, with an anxious expression and suffering intensely. Her favorite position was a sort of sitting posture, with the body bent forward and to the right, and with the lower limbs flexed strongly upon the abdomen. The symptoms already described were very marked; also irregular attacks of chilliness or rigors; temperature was elevated every night; there was no cough, jaundice, or vomiting; there was, however, sallowness of the skin, and quite dark, turbid, and scanty urine.

Examination revealed a dark bluish swelling some three inches in diameter in the right hypochondriac region, bordered by the sixth rib above; the tenth below; the linea mammalis (a line extending perpendicularly downward from the right nipple), upon the inside; and the linea axillaris on the outside. The swelling was about three-quarters to one inch in height, and presented all the appearances to sight and touch of a carbuncular development. It was hard, firm, and quite painful to the touch. There was no fluctuation. My first object was to ease the child of her enforced or assumed cramped and painful position in bed by encouraging her to occupy a rocker, or, if possible, to step about the room a a little. She was put upon concentrated nourishment, stimulants, and medicinally, on syr. ferri iodidi, and bromides and chloral for the pain. The latter remedies had to be early replaced by opiates and quinine, owing to their inefficiency to combat suffering. Temporarily, I ordered an ointment applied every eight hours, composed of camphor, opium, ext. belladonnæ, comp. resin ointment, and cosmoline.

This plan of treatment was continued for five or six days, with the effect of markedly softening the swelling and causing it gradually to diminish in size, and the development of a central point of concentration just over the eighth intercostal space. I thought I detected fluctuation on palpation, but obtained nothing but blood on aspiration with the exploring needle.

At any rate the child seemed easier and more comfortable. Anodyne flaxseed poultices were now started, and on the 21st instant I prepared to operate, all the conditions seemingly pointing to the detention of deep-seated pus. Contrary to the usual custom, I determined to treat the case by free incision, the thorough evacuation of the pus (if any), and the prevention of reaccumulation by complete drainage by means of rubber tubing.

The little patient was thoroughly etherized, and, after selecting a favorite point by the aid of the exploring needle, a free opening was made, one inch or more in length, down through the eighth intercostal space, about one and a half inches to the right of the linea mammalis. Immediately a large quantity of pus flowed from the wound. The amount of pus I judged to have been at least eight fluid ounces.

At first the pus was "laudable," free from odor, but streaked or marked with biliary coloring matter; toward the end it assumed the very dark condition usually spoken of as "chocolate-colored pus," due to the presence of blood or disintegrated hepatic tissue. Gradual pressure over the hepatic area aided in its rapid and free evacuation; the bulging over the intercostal spaces disappeared, and for the first time the outlines of the ribs were readily recognized. A probe was now passed through the wound under the ninth rib, and it entered in an obliquely downward direction, to the extent of four inches, toward the linea alba, and three inches obliquely upward toward the sternum, in depth perpendicularly about two and a half inches.

A perforated rubber drainage tube doubled upon itself was introduced into the depth of the cavity, enabling free drainage; and the daily injection of carbolized oil (two to sixteen fluid ounces) through one end, and its escape through the other. Warm cataplasms were continued night and day. After some five days the tube was replaced by one of a smaller calibre, and entirely done away with the ninth day after the operation. A small piece of lint dipped in carbolized oil was used a few days longer, simply to keep the cut from closing and insure thorough healing from within outward. Finally, carbolized zinc ointment completely healed the wound by December 8th. Her improvement and rapid convalescence after the operation were wonderful. Internally she has

been taking cod-liver oil emulsion with hypophosphites and syrup ferri iodidi.

December 12th, she was walking and playing about her room. Of course, the marked constitutional depression due to her serious ailment will, to a considerable extent, continue for some time to come, but there is at present no doubt of her entire recovery of good health.

Later, January 15, 1887, the child is well and fully recovered.

Remarks.—Let us notice briefly some of the very interesting features presented by this case. The first thought worth noting is the tender *age* of the patient, viz., twelve years. The statistics show this serious ailment to be unusually rare in children, being seldom seen under the age of twenty.

In seeking for the *cause* of the disease in this case, I am led to adopt one of a traumatic nature. Frerichs, Budd, Andral, Romis, Morehead, and others, in their collection of cases, show but a very small percentage due to external violence. Thus, Budd reports only 2 out of his 62 cases collected; Morehead, but 4 out of his extensive observations—318 in all. After the closest questioning, my little patient revealed no previous malarial, dysenteric, metastatic history, or any other inflammatory and ulcerative process in the gastro-intestinal canal, which are generally looked upon as the chief disturbing influences or causes of suppurative inflammation of the liver. Careful inquiry elicited the following history and probable cause:

About four days previous to the commencement of her symptoms, she assisted her aunt in carrying flower plants from the yard up to the fourth floor of the house. One of these plants was, owing to its weight, entirely beyond her strength; yet, after four efforts, she succeeded in landing it on the fourth floor. She described very vividly the pain caused by the pressure, and the weight sustained over the right hypochondriac region in her struggles to complete her task. As before said, the child is of a very spare build and delicate physically, and it is quite probable that this external violence originated her painful affection.

A few words as to the diagnosis, prognosis, and treatment. I found much difficulty for a time in arriving at a satisfactory conclusion as to the *diagnosis* of the disease, and was inclined for some days to believe the case one of an unusual carbuncular development, dependent upon a very badly run-down system, and having its starting-point in the mechanical violence or external contusion referred to above. Even the exploring needle failed me in establishing a positive conclusion. It was only quite definitely arrived at by doing as Frerichs so aptly puts it: "In most cases a correct diagnosis will only be arrived at by not relying upon individual symptoms, by taking a general view of the mode of origin and entire clinical history of the case, and, after excluding by comparison the diseases of the liver and of the neighboring parts, which may give rise to symptoms similar to those of hepatitis."

It is well understood that the prognosis is generally unfavorable in suppurative hepatitis. Frerichs says: "Suppurative hepatitis belongs to the class of severe maladies which imperil life, and which terminate in death far more frequently than in recovery." And this naturally leads to the consideration of the treatment. I candidly believe from the presence of the grave symptoms, that my patient would have died in a short time but for the prompt and energetic operation undertaken as soon as a reasonable conclusion could be arrived at concerning the diagnosis. Even when there is considerable doubt existing, and the condition of the patient is serious, careful exploratory incision could be made to determine the true nature of affairs. No danger can result from this when proper precautions are used. At any rate, the aspirator should be early used as a means of establishing diagnosis. Drs. Sims, Hammond, Jimney, of Mexico, and many others, have frequently punctured the liver without any bad results.* It has been demonstrated time and time again that the entrance of air into such a cavity through an incision is not necessarily attended by decomposing action and death, but, on the contrary, a complete evacuation is obtained, reaccumulation prevented, and the threatened death by exhaustion or blood-poisoning averted. Upon the other hand, imperfect removal of the pus by one or more aspirations or punctures, permitting more or less to remain behind, will, in addition to that constantly forming, undoubtedly keep up the constitutional disturbances, and, finally, produce a fatal issue by rupture or blood-poisoning, if the very rare act of absorption does not take place.

The case treated of in this paper happily illustrates the good results of free incision, perfect drainage per tube, and the rapid healing and antiseptic properties of carbolized oil. The method of gradually opening the abscess as recommended by Récamier, Begin,

*Since completing these remarks, I notice in the January 1st number of the Medical News, a report of a "Case of sudden death from the introduction of an aspirator needle," by Dr. Reeve, of Dayton, Ohio.

and others, by the separation of a slough through many applications of caustic potash or soda, is very slow in operation, painful, productive of loss of tissue, and if an opening into the pus cavity is finally established air must also surely enter. Again, many abscesses of the liver open spontaneously, and though air freely enters the cavity, the patients usually go on to rapid recovery. In fact, this latter mode of termination of the disease (spontaneous opening) is very much welcomed by the physician, and has eminent advocates. I should not think, after the excellent result obtained, of treating similar cases by any other plan than the one suggested. Lives are undoubtedly lost by the partial or imperfect method of the removal of foreign material by repeated aspirations or punctures, thereby necessarily keeping up the source of trouble which eventually must end in death. The early and prompt operation happily terminated my case in recovery in about fifty days, while Rouis, in his valuable and extensive statistics, shows the average duration of the disease in cases *not* operated upon, and which recovered by bursting either through the thoracic or abdominal walls, through the bronchi, colon, or stomach, to have been 140 days.

DISCUSSION.

Dr. C. N. Seltzer said: "I have seen three cases of abscess of the liver, and in these cases the symptomatology was somewhat different from that of the case described. I should think that an abscess of the liver holding eight ounces would produce more constitutional disturbance that was present in this case.

"The destruction of liver structure is usually greater, and the case, as a rule, requires a longer time for recovery. The three cases which I have seen all resulted fatally, and at the post-mortem the liver tissue was found to be very ragged, and hanging in shreds in the abscess cavity. In these cases the diagnosis was readily reached by a microscopical examination of the pus. The liver cells could be easily detected. That I think should have been the mode of determining whether the case were really one of hepatic abscess or not."

Dr. Joseph S. Neff said: "It is well known that pus from a hepatic abscess rarely contains liver débris, because most abscesses in this situation are surrounded by dense walls of pyogenic membrane. The cases to which Dr. Seltzer has referred, in which the liver substance projects in shreds into the abscess cavity, are cases of diffused abscess, which are very rare.

"In the circumscribed abscesses of the liver which I have seen, the tendency to point has been in a different direction from that in the case reported. I have seen only one case in which the abscess was opened through the abdominal walls. That was the case of a man in the Jefferson College Hospital. The abscess was tapped a number of times, but as the man was evidently sinking, it was decided to open it through the abdominal wall. One of the dangers of this operation is that pus may escape into the abdominal cavity. In performing this operation, some operators at the first sitting cut down to the peritoneum. In the course of twenty-four hours there will have been some local peritonitis with the formation of adhesions, and then the operation is completed. Dr. J. M. Barton operated in my case, and after cutting through the abdominal wall with a scalpel, a white-hot knife was used in order to avoid hemorrhage from the liver structure. After the liver had been penetrated to a short distance, the knife failed to act satisfactorily, and the operation was completed with a soft gum catheter.

"In the case reported, the cause of the affection and the youth of the patient are also points of considerable interest."

Dr. Seltzer said: "My remarks were based on the statement that this was an acute diffused hepatic abscess, and not one surrounded by pathogenic membrane."

Dr. Vogler said: "I have no doubt whatever as to the diagnosis of this case. The situation of the abscess, the fact that the pus was mixed with biliary matters, the fact that the finger could be introduced through the cut two inches under the ribs, and the very grave constitutional symptoms, were sufficient to indicate the seat of the disease. I unfortunately neglected to make microscopical examination of the pus. As Dr. Neff has said, it is not necessary that disintegrated hepatic structure shall be found, for many of these abscesses are localized. I thought that in all probability adhesion had formed between the abdominal wall and the liver, and in operating I experienced no trouble."

Dr. Joseph S. Neff read the report of

A Case of Perforating Ulcer of the Stomach, with Chronic Peritonitis.

Alfred Reed, colored, stevedore by occupation, forty-five years old, was admitted to the medical ward of the Philadelphia Hospital, December 12, 1886. The family history was indefinite; he had had the ordinary diseases of childhood; pleurisy when about nineteen; enteric fever a few years later; says he had relapsing fever about twenty

years ago, since which time he has often had pains and stiffness in the joints, but not severe enough to prevent him working. During the last year he has had occasional attacks of indigestion, rarely accompanied by nausea and vomiting. Last spring he vomited blood; had sensations of burning heat in the stomach, and other evidences of indigestion, with extreme acidity of the stomach; there was very little pain until the latter part of July or the first of August, at which time it was confined to the abdomen (?), and was constant, but more marked after eating. From this time he vomited after almost every meal, and it was not long before he could retain only liquid food. At first the vomited matter was simply the undigested food, later small quantities of a slimy, watery fluid as well. From that time up to admission he vomited blood, dark in color, small in quantity, but once or twice.

Does not remember any sudden onset of pain, or any symptom pointing to perforation of the stomach, or acute peritonitis. His weight last winter was one hundred and ninety pounds, but at date of admission he was much emaciated, complaining of severe and constant pain over the upper portion of the abdomen, especially in left hypochondriac region, not being able to bear the slightest pressure. There was a small prominence, slightly firmer than the rest of the abdominal wall, situated below the margin of the ribs, one inch to the left of the median line, ovoid in shape, the horizontal diameter being three inches, the vertical diameter two inches in length. Over this area the percussion note was somewhat dulled—*i. e.*, on light superficial percussion; the motion of the diaphragm was not imparted to the mass. He referred to this point as the source of pain which radiated over the entire abdomen and through the back.

Physical examination showed the heart to be of normal size, first sound absent, second accentuated, more marked over aortic valve; no murmurs were heard; the temporal and radial arteries were firm and hard, not compressible, with no perceptible pulse in the wrists. A systolic bruit was heard posteriorly over the thoracic aorta.

The lungs were normal, but many mucous râles were audible in the bronchial tubes.

No increase in the liver or splenic dulness could be made out, as he could not bear any pressure below the diaphragm.

His general condition improved somewhat for a short time after admission; the pain, however, remained constant, and vomiting was of frequent occurrence.

He died of exhaustion on January 1, 1887. During the time he was under observation no change of note occurred. The temperature ranged from normal to 99.5°. He vomited blood once only, on December 15th, small in quantity, and dark in color. Paroxysmal spasm of the diaphragm commenced December 16th, and lasted with intermissions until death. A loud systolic murmur was detected on the 19th, with area of intensity over the apex. The urine remained normal throughout, and much reduced in quantity; specific gravity 1.032; reaction markedly acid, and of high color. No albumen or sugar.

The diagnosis was made of cancer of the pyloric end of the stomach with secondary peritonitis, induration with inflammatory infiltration, and adhesions between the diaphragm and the stomach.

Autopsy.—External Appearances. — Body much emaciated. Abdomen scaphoid.

Thorax.—Lungs were normal, except hyperæmia, and were firmly adherent to the diaphragm. No other pleural adhesions.

Heart.—Pericordial sac obliterated by adhesions. Left ventricle large, firmly contracted. Right ventricle small, and partly filled with a firm clot. Valves normal. Aorta shows marked chronic endarteritis throughout its whole thoracic portion, and extending to abdominal aorta. Left ventricle was small, wall thickened, red and firm.

Abdomen.—Peritoneal cavity contained a quantity of purulent (?) matter. Peritoneum inflamed, the coils of intestine extensively adherent to each other, and to the liver, spleen, stomach, and diaphragm. There was a sac formed at the hilus of the liver by adhesion of the duodenum with the gall-bladder and under-surface of the liver. This cavity contained purulent (?) fluid with thickened walls. The gall-bladder was flattened from pressure, and contained a small amount of thickened bile. The mesocolon showed inflammatory thickening. The upper surface of the liver was extensively adherent over the right lobe to the diaphragm. The left lobe was intimately connected with the stomach. There was a cavity formed by the anterior surface of the left lobe of the liver, the anterior surface of the pyloric end of the stomach with the diaphragm forming its roof. The right wall of the cavity was formed by the suspensory ligament of the liver, the anterior wall by adhesion of the liver and stomach, the left wall by adhesions between the diaphragm and the anterior wall of the stomach. The cavity was filled with

a grumous material, its walls being indurated and inflamed. In the floor of the sac there was an opening a half inch in diameter through the anterior wall of the lesser curvature, about half way between the cardiac orifice and the pylorus, and a half inch to the left of the left edge of the left lobe of the liver. There was also another sac formed by adhesions between the diaphragm, spleen, and cardiac end of the stomach. This appeared to be a blind cavity, having no communication with the one just described, or the stomach; it contained a similarly looking thick grumous fluid.

Stomach.—Walls were greatly thickened, more marked at the lesser curvature. In the neighborhood of the perforation noted the wall was thinner, the orifice presenting a rounded edge. When opened, the mucous surface thoughout appeared greatly ridged and mammilated, general thickening being most marked at the pylorus. There was no indication of neoplasm.

Spleen.—Adherent throughout its whole surface, very small, firm, with dark red fibrous pulp.

Liver.—Right lobe large, the left being small. Flabby cut surface shows a slightly congested parenchyma.

Pancreas.—Normal.

Kidneys were firm, cyanosed, normal in size; capsule slightly adherent; some small cortical cysts; thinning of cortex, and interstitial thickening.

The point of interest clinically is in connection with the diagnosis from malignant disease.

The constant character of the pain, the persistency of the vomiting without remissions, the small amount and character of the hemorrhage, the gradual loss of flesh, with apparent cachexia, and the presence of a painful, non-fluctuating tumor, would warrant a diagnosis of cancer. I should mention, too, the presence of constipation as being of some value.

The circumscribed cavities noted were the result, evidently, of inflammation from the passage of the contents of the stomach into the peritoneal cavity, the secondary adhesions binding the organs together in such a form as completely to shut off the small cavity in the left side from any outlet, while the larger in the right side still had direct connection with the interior of the stomach. The cause of the immobility of the tumor upon deep inspiration was undoubtedly due to the fact of the diaphragm itself being thoroughly adherent to the chest-wall over a considerable extent of its surface, and therefore having very little play during the respiratory movements.

DISCUSSION.

Dr. Henry F. Formad said: "The case of Dr. Neff's is of great interest from the fact that the patient's life was considerably prolonged by the formation of a sac which retarded the development of peritonitis after the rupture of the ulcer. The case is also interesting from the fact that it occurred in a male. In some twenty-two cases of gastric ulcer in which I have made the post-mortem, in about seventeen the subjects were females. This agrees with the experience of others. Gastric ulcer is not a rare condition, but many cases are overlooked because physicians are in the habit of opening the stomach through the smaller curvature, and it is here that the ulcer is most frequently situated. In the majority of cases that I have seen, the death was sudden, being due to perforation. In some the death was apparently due to shock, the whole of the contents of the stomach having in many instances escaped into the peritoneal cavity. Death occurred before there was time for the establishment of inflammation. In some cases there was free hemorrhage, and in one case there was a complete blood-cast of the stomach.

"Some of the cases that I have seen have been in drunkards, some have been in hysterical women, and some in the insane. Three of my cases came from the Insane Department of the Philadelphia Hospital. Dr. Dercum informs me that he has met with several cases of gastric ulcer among the inmates of the Norristown Insane Asylum.

A Dog That Goes on a Toot.

There is a very funny dog in Chicago. He belongs to a saloon-keeper, and his most remarkable trait is his inordinate passion for strong drink. He loves his toddy, and he appears regularly at 7 o'clock each morning to have two fingers of forty-rod poured down his throat through a funnel. This dog often gets drunk, and the effect of the liquor on him is nearly like its effect on man. He dances around at first and gives forth incoherent and unaccountable yelps, but after a few more drinks his eyes lose their fire. He whines in a maudlin manner. His steps become unsteady. He is drunk. He goes to sleep behind the stove, and awakens with a throbbing brain to take an application of cracked ice, and to cool his fevered tongue with a cocktail, for all the world like a disreputable rounder.

Periscope.

Paroxysmal Tachycardia.

In a clinical lecture recently given at the General Hospital of Vienna, Professor Nothnagel directed the attention of the audience to a very rare and interesting case of "paroxysmal tachycardia, combined with failure in the heart." On the forenoon of October 6th, the patient, aged 36, was admitted into the hospital, the number of pulse-beats being at that time 120 in the minute. In the afternoon it was 144; on the next morning 90; during the following day 84 and 82; on October 9, morning, 82; in the afternoon, 138: on the morning of October 10, 178; at eleven o'clock the same day 170, and soon afterwards 182; on the morning of October 11, 84, at half-past ten o'clock 176, at four o'clock 132, at five o'clock, 144; the next morning at eight o'clock it was 176, at nine o'clock 144, at ten o'clock 146, at eleven o'clock 134, at mid-day 144, at four o'clock 168, in the evening 164; on October 13 it was 92 in the morning, at nine o'clock 88, and soon afterwards from 170 to 180. This acceleration of the pulsations lasted from half-past one till half-past three; at five o'clock the patient's pulse was 96. On October 14 it was 72; on the 15th 76, and so on, the number of pulsations being again normal. The temperature was normal throughout. The patient was seized with these paroxysmal attacks without any apparent cause, and they were very variable in duration. On one occasion the paroxysm lasted for two hours, another time about two days: the longest duration was from three to four days; the average duration was from one to one and a half days. The attacks occurred without any artificial stimulant whatever, such as coffee or tea, nor were they caused by any psychical irritation; they showed no gradual transition, but came on and ceased quite abruptly. The patient happened once to be seized with a paroxysm of 176 beats immediately after laying down a book, the contents of which had not interested him in the least. The attack was accompanied with a feeling of anxiety, but Professor Nothnagel emphasized the fact that this anxiety was not such as was mte with in angina pectoris. All the other characteristic symptoms of that affection were absent in the case in question. The attack disappeared quite suddenly, and the patient stated that he had then the feeling "as if something would fall away." The patient further stated that he "sometimes succeeded in suppressing the attack by a deep and prolonged inspiration, especially if he at the same time drank a glass of cold water." Professor Nothnagel told the patient to do this during an attack, and after the patient had swallowed half a glass, Professor Nothnagel was able to state that the number of the pulse-beats had decreased quite suddenly; he felt three slow and large beats, and soon afterwards the number of the beats was again about 180. Professor Nothnagel also made other experiments; he told the patient to swallow a spoonful of common salt; he compressed the crural nerve very strongly, and wound a thread around the upper extremity, but these manipulations produced no effect. The patient himself stated that the draught of cold water had not much to do with the cessation of the attack, but that it was chiefly due to the deep inspiration. Professor Nothnagel remarked that some cases of paroxysmal tachycardia were to be found recorded, but that paroxysmal tachycardia in cases of organic heart disease was very rare, and that he did not remember any similar case in medical literature. As to the explanation of this phenomenon, the lecturer said that of course there was no doubt that one had to do in such a case with a disturbance of innervation, but that the question as to what nerve-tracts were affected was very difficult to answer. As to the existence of an accelerator-nerve of the heart in the human species, this was still a matter of dispute. Only two nerve-systems could be taken into consideration in the case in question—the pneumogastric and the musculo-motor apparatus in the heart. It was conceivable that there might be some irritation of the cardiac musculo-motor apparatus in the substance of the heart itself; or again, there might be sudden paresis of the vagus. It was very difficult to decide which explanation was correct in this case, but according to the impression the lecturer had received from the observation of one of the attacks, he was rather inclined to the latter view. One might suggest that, in the same way that intermittent paralysis occurred in other motor nerves, such intermittent functional paralysis might also occur in the vagus. Professor Nothnagel thought it very probable

that this hypothesis was correct. As to the fact that the patient could stop the attack by taking a deep breath, Professor Nothnagel pointed out that this feature of the case was very remarkable, inasmuch as the pulse was usually quickened by deep inspiration. He offered the following explanation of the anomaly. When a deep inspiration is made, the ends of the vagus in the parenchyma of the lungs are pulled and twisted. This produces an irritation of the sensitive ends of the vagus in the lungs, and, at the same time, a reflex retarding action on the vagus of the heart. The fact that artificial irritations, like swallowing common salt, compression of the upper extremity, faradization of the epigastrium, and so on, did not produce any effect, could not be looked upon as negativing this theory, as they might not have been sufficiently strong to act suddenly on the vagus. On the other hand, it was known that there were connections between the different fibres of the vagus. There were persons who complained of dyspnœa without suffering from any affection of the lungs or the heart. It was not rare that such individuals suffered from dyspeptic symptoms, and the lecturer had observed in a series of such cases that the dyspnœa disappeared when the digestion was rectified. Hence there existed connections between the vagus of the stomach and that of the lungs, and it was therefore very possible that retarding impulses were transmitted from the pulmonary to the cardiac vagus.

Hydatid Cyst of the Liver.

At a recent meeting of the Société Médicale des Hôpitaux, M. Guyot related the case of a military officer, aged twenty-four, who had a hydatid cyst of the liver. In September, 1885, the patient complained of excessive fatigue, and of severe pain in the lower part of the chest on the right side. He had complete loss of appetite, pain after taking food, profuse perspiration, with fever at intervals. Percussion revealed dullness in front of the nipple, extending to the edge of the false ribs. On auscultation, pleural friction was heard. There was no cough, nor expectoration; the tongue was very foul. M. Guyot diagnosed pleurisy, without effusion and gastro-intestinal disturbance. The symptoms persisted, and the pain (which was very severe in the fore part of the chest) extended to the right shoulder. M. Guyot believed that the case was one of hepatic congestion, and rejected the possibility of tuberculosis. M. Potain examined the patient, and diagnosed pulmonary tuberculosis. He recommended the baths and waters of Amélie les Bains. M. Garnier, of that place, entirely coincided with M. Potain's diagnosis, although he thought there was coëxisting congestion of the liver. After the patient had been on milk diet for three months, he appeared completely cured. He resumed his profession, but soon fell ill again. There was evidently hepatic congestion, and submucous *râles* could be heard in the chest. On returning to Paris, in May, 1886, M. Guyot found the same symptoms as in the previous year. The patient was examined by M. Hanot, who diagnosed diaphragmatic pleurisy, unaccompanied by any liver complaint; he advised a blister, and a course of treatment at Mont Dore. The patient's condition, however, became more and more alarming, and hypodermic injections of morphine were required to relieve the severe pain. Diarrhœa and nervous excitement came on, and the visit to Mont Dore was given up. On fresh examination, M. Millard suspected suppurating cyst of the liver, and advised puncture. In July, the patient was seized with attacks of vomiting, fœtid diarrhœa, and aversion to food. M. Guyot made two punctures, which gave issue to pus. Two days later, M. Duplay punctured with a large trocar, and drew off 800 grammes of pus mixed with blood. A few days afterwards two thick membranes, accompanied with blood, were passed in the stools of the patient, which M. Guyot considered to be the remains of the cyst. Microscopic examination revealed the presence of hooklets in the membranes. The condition of the patient became more and more alarming, and notwithstanding two transfusions of blood, injections of ether, and a large blister on the epigastric region to arrest the vomiting, which was incessant, the patient died in a few days. M. Guyot thought that if hydatid cyst of the liver had been diagnosed in May, laparotomy might then have saved the patient's life, though, as the cyst reached as far as the convex surface of the liver, the fatal issue was, perhaps, inevitable.

At the same meeting M. Ollivier referred to the case of an officer from Tonquin affected with hæmoptysis, night-sweating, and diarrhœa. On examination, there were no signs of pulmonary disease, but the liver was enlarged to a third more than its natural size. On examining the sputa, M. Ollivier detected the presence of hooklets. It was clear that there was hydatid cyst of the liver opening into the lung. The patient would not allow the cyst to be punctured, and died.

Gelle on the Sensibility of the Tympanum on Receiving the Direction of Sound.

When a sound strikes the ear, it is referred to that part of the horizon towards which the organ is directed at the moment of the most intense sensation. The knowledge of the fact that the sound-producing body is outside us, and the notion of the direction in which it lies, are thus acquired at one and the same time. How is the result obtained? The knowledge as to the side from which the sound comes is furnished by the fact of our hearing it on the right or on the left, and also by the consciousness of the muscular effort required to perceive it. It is necessary, however, that this effort should itself be guided; and this is brought about by the sensibility to sound of the skin of the concha, the side of the neck, and the face. This, at least, is the opinion of distinguished physiologists like Weber, Schneider, and Voltolini. Hartmann and others attribute the perception of exteriority to the sensibility of the tympanum alone. The cutaneous surface of this organ being struck by the sound wave gives rise to the sensation indicating its source and direction. This theory has never been contested; but the effort to perceive the direction of sound is probably better explained by the consciousness of the movements of the head and of the body in seeking for its maximum intensity. Dr. Gellé purposely omits examining the part which the concha plays as a screen in this effort, as this has already been well demonstrated by Küss and Duval; but he has been able to solve the remaining problems on this subject through observations on two patients in M. Charcot's wards. The first was a man, affected with general anæsthesia of the skin, with trembling and want of equilibrium, but whose intellect, as well as his sight and hearing, remained intact. Anæsthesia was so complete on both sides that a piece of ice placed in the hollow of the ear produced no sensation whatever; the organ remained likewise insensible to ether spray, and to the infliction of deep wounds with the point of a needle. Both tympana were touched with a needle, the effect being observed through a mirror and speculum. It was found that the membrane might be touched and pricked without the patient's having the least sensation either of pain or of contact. The patient's hearing was good, and he replied perfectly well to questions, whether he was spoken to from before or from behind. Placing himself behind the patient, M. Gélle directed him to close his eyes, and then held a watch within a few inches of his right, and then of his left ear. The tick was distinctly heard by the patient, but when asked on which side, he was unable to say with his eyes closed. The experiment was repeated, always with the same result. Hence, M. Gellé concludes that the sensibility of the tympanum plays an important part in the effort to perceive the direction of sound. He pursued his inquiries upon several other patients affected with general anæsthesia, and found that in all those who could distinguish the side on which the watch was placed, the tympanum retained its sensibility. It is evident, therefore, that the tympanum is sensitive to the vibrating sound-waves, and this sensibility gives us the notion of exteriority and of the direction of the sound.

The Treatment of Compound Depressed Fracture of the Skull.

Dr. Philip E. Muskett has published, in the *Australian Medical Gazette*, October 15, 1886, a paper on the "Claims of the Immediate Operation in Compound Depressed Fracture of the Skull." The author advocates early operative interference in such cases, and, to support his views, refers to a previous report of seven recoveries in thirteen cases under the care of the Honorary Surgical Staff at the Sydney Hospital during a period of fourteen months, and gives in this paper an analysis of twelve more successful cases of compound depressed fracture of the skull treated by operation. With regard to the indications and objects of such treatment, Dr. Muskett seems to hold views similar to those that have lately been expressed by Dr. Wagner, of Königshutte, who is of opinion that the trephine should be used not so much for relieving or preventing compression as for guarding the patient against septic inflammation. Dr. Muskett gives the following as the after-results to be feared in cases of compound fracture of the skull, if the depressed fragments are not elevated or removed, and perfect drainage insured:

1. Septic meningitis setting in on the second or third day after the injury.
2. A spreading encephalitis, perhaps running on to suppuration, with extensive destruction of the cerebral tissue.
3. If the dangers of acute inflammation have passed off, death may result from softening around the injured part.
4. Subacute encephalitis, which may follow even at a remote period.
5. The irritation of the splinters from the inner table may eventually cause chronic meningitis, terminating in suppuration.

6. The same condition may induce traumatic epilepsy.

In supporting the practice of early surgical interference without waiting till symptoms of compression declare themselves, Dr. Muskett suggests that, if such were not the rule, the time for operation would pass by in too many cases; for it cannot be too strongly insisted upon that the removal of depressed fragments is essentially a procedure for preventing the development of inflammation in the membranes of the brain. In answer to the objection of trephining being a grave operation, Dr. Muskett holds that the application of the trephine, or, what is more preferable, of Hey's saw, is not dangerous in comparison with the risk incurred of leaving osseous splinters imbedded in the dura mater; and, in proof of the encouraging results of such operative intervention, refers to the records of cases that have been treated by himself and his colleagues at the Sydney Hospital.

Reproduction of the Syphilitic Virus.

Professor Neumann made at the last meeting of the Imperial Society of Physicians of Vienna an interesting communication, which is a very important contribution to the doctrine of syphilis. In a paper which he read on the Different Centres of Reproduction of the Syphilitic Virus, he first discussed the opinions of Virchow and Baerensprung as to the anatomical changes which were to be found in parts of the skin and mucous membrane of individuals who had been affected with syphilis. The speaker then communicated the results of his own researches, and said that, after all clinical symptoms of the syphilitic affection had disappeared, he nevertheless met with numerous exudation-cells of a round and spindle-shaped form in the skin and mucous membrane. These cells, which were very infectious in the recent stage of syphilis, augmented and proliferated very quickly. In the recent stage they could infect healthy individuals if these were deprived of the epidermis. As to the tertiary stage of syphilis, the exudation-cells grew and augmented much more slowly, were less infectious, irritated the neighboring tissue to inflammation in a less degree, and did not spread on other localities when proliferating and augmenting. In a later stage they inclined towards the formation of connective tissue and hypertrophy, and at last underwent a caseous and destructive process. Hence these exudation-cells were always present in the skin and mucous membrane during the latent state of syphilis, and continually formed a source of danger for the health of the individual. The patients in whom the clinical symptoms of syphilis had already disappeared were, therefore, by no means to be looked upon as cured. Anti-syphilitic treatment should be continued; but as the ordinary remedies like mercury, iodide, and their preparations, when continued for a long time, seriously affect nutrition, the therapeutical task became very difficult. The speaker illustrated his opinion by some cases which had come under his notice. Among other specimens, Professor Neumann examined the tissue of the cutis of that part of the perineum on which swellings and moist papules were so often observed, taken from individuals who had suffered from syphilis a year before. Though this part did not show any abnormal change externally, he found considerable changes in the microscopical examination. The tissue of the cutis was infiltrated with round cells, the vessels dilated, their endothelial cells as well as their nuclei enlarged; in the adventitia and the perivascular tissues there was a great number of granulation-cells; moreover, there were numerous transverse sections of lymphatic vessels. Another interesting case reported by Professor Neumann was that of a person who had been affected two years ago with a maculous syphilide, psoriasis, and papules on the lips, and who had been treated at the speaker's *clinique*. Microscopic examination of the mucous membrane of the lower lip of the individual in question, though outwardly normal, showed, in the subpapillary layer, crowded vegetations of round cells and enlarged papillæ.

Loss of the Knee-Phenomenon in Diabetes.

Professor Bouchard recently drew attention to the loss of the knee-phenomena, as an important element in the diagnosis of diabetes. In a recent article in the *Revue de Médecine*, MM. Marie and Guinon gave the results of fresh observations, which confirm the importance of this symptom. They also point out how it may, in certain cases, lead to error. Among the diseases in which the loss of reflex movement is most frequently met with is tabes. If a patient presents the following symptoms—abolition of reflex movement, lightning pains, slight staggering when the eyes are closed, gradual loss of sight, difficulty in micturition, diminution of sexual power—the evidence points to the existence of tabes. If, however, there be sugar in the urine, all these symptoms may safely

be attributed to diabetes. It is to such cases that the term pseudo-tabes in diabetes has been given. MM. Marie and Guinon having for a long time sought in vain to find sugar in the urine of patients suffering from locomotor ataxy in M. Charcot's ward, conclude that the phenomenon is sufficiently rare in tabes to warrant the diagnosis of diabetes in all cases where sugar in the urine is found in connection with the above symptoms. It may be remarked that the degree to which the movement is abolished fluctuates with the severity of the disease itself. Aggravation of the malady is followed by loss of the movement, whereas improvement, whether from treatment or otherwise, causes it to reappear. The disappearance of the phenomenon does not indicate a special form of diabetes, and cannot be made the basis for a nervous theory of this disease. It simply shows that the affection has entered on a new phase, being no longer a balance between the incomings and outgoings of the system; the patient is subject to all the terrible complications of diabetes, which are the most frequent causes of death in diseases of this kind. As regards the prognostic value of the symptom which M. Bouchard has indicated, nothing can be more convincing than the following carefully collected statistics: Out of a first series of 66 patients, 47 retained the power of reflex movement, while 19 had lost it. Of these 47 cases, 2, or 4.25 per cent., were fatal. Of the 19 who had lost the power, 6, or 30.3 per cent., were fatal. In another series of 111 patients, 70 possessed the power of reflex movement, and 41 have lost it; of the 70 cases, 5, or 7.14 per cent., proved fatal, while of the 41 cases in which the power had disappeared, 7, or 14.63 per cent., were fatal. That is to say, the mortality in the cases in which the power of reflex movement had disappeared was more than double that in the others.

A Successful Treatment of Acne.

Dr. John T. Metcalf thus writes in the *Boston M. and S. Jour.:*

Judging from my own experience, I do not think the ease with which acne, whether of the sebaceous, pustular, or papulous form, is curable by external means, is generally very gratifying to patient and practitioner. For the last seven years I have not failed in a single instance to cure the ten or twelve cases which have come under my observation.

Some have been of long standing and of great severity. The last very bad one was facial, and so disfigured the doctor to whom the face belonged, that he only went into society with the greatest reluctance. When I told him that I felt sure he could be greatly benefited, and that I thought he could be cured, he said he had given up all hope of amendment, and had made up his mind to practice philosophy in accepting the inevitable.

I met my confrère a week ago, and actually failed to recognize him at first, so entirely was his face free from the disfiguring acne.

I was led to employ chrysophanic acid in these cases, by reason of learning what it had effected when used as an ointment in treating chronic psoriasis. My habit is to begin with an ointment made of three grains of the acid to an ounce of vaseline. The face is well washed with soap and dried, at night. Before going to bed, the parts in which acne exists are well rubbed with the ointment, and this is repeated every night, until a sharp dermatitis with scarlet skin is produced. Inunction then ceases, until disappearance of the artificial inflammation of the skin, when a repetition of the ointment is made, under conditions above stated.

Is Tetanus Contagious?

At the Société de Chirurgie, an interesting paper, as we learn from the *Lancet*, followed by discussion, was read by M. Larger, which seemed to show clearly that there were good grounds for believing in the contagiousness of tetanus. Four patients who had been treated in the Colmar Hospital, were seized with tetanus at different intervals, and all died. The nature and severity of the wounds varied in each case from an amputation to a simple incised wound. The only thing common to them all was that the cases had all occupied contiguous beds. Tetanus is rare at Colmar. None of the patients had had anything to do with horses. A veterinary surgeon, M. Cagnat, had practiced castration on horses for twenty-five years without a single case of tetanus. At the end of 1884, he removed with an écraseur a tumor of the testicle in a horse; the animal died of tetanus. Operations for castration practiced with the same écraseur on five horses afterwards, were followed by tetanus and death in all the animals. The écraseur was then submitted to disinfection by being heated to a high temperature. The instrument was afterwards used for fresh castrations, and without tetanus resulting in any of the animals operated on.

Soft Chancre in the Middle Ear.

Dr. Guranowski, a Polish physician, relates (*Vratch*, No. 28, 1886,) the case of a woman with phagedenic chancre of the genitals, who, when snuffing tobacco, transmitted the virus to the nasal mucous membrane. Several small ulcers, with profuse offensive discharge, appeared on the nasal septum and inferior turbinated bones. In the course of time the chancrous matter penetrated from the nasal cavity through the Eustachian tube into the middle ear, and gave rise to acute purulent inflammation of the part, with pain, deafness, and subsequent perforation of the tympanic membrane. Profuse otorrhœa followed, and the external auditory meatus became also ulcerated. The patient was treated by introducing iodoform powder into the meatus and nasal cavity, and by irrigation with warm water through a catheter introduced into the Eustachian tube. In four weeks hearing was restored, and the patient improved generally. Dr. Guranowski especially draws attention to the irrigation of the middle ear, which procedure gave in his hands excellent results, even in such cases where trepanation of the mastoid process seemed to be the only means for saving the patient's life.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The *Southwestern Medical Gazette*, Vol. I, No. 1 (January, 1887), is on our table. It is a monthly, $1.00 a year, and has for editors Drs. M. F. Coomes and J. B. Marvin. It is published at Louisville, Ky.

——In a recent reprint, Dr. Orpheus Everts sets forth several common errors in relation to insanity.

——In a report on rhinology, especially the treatment of naso-pharyngeal catarrh, Dr. J. A. Stucky states as follows the three indications, or objects, of the local treatment of diseases of the nasal and pharyngeal cavities:

First, non-irritation.

Second, thorough cleansing of the diseased surface, with sufficient force to remove the morbid secretion.

Third, medication and protection of diseased tissue, without irritation of healthy tissue.

——Two short essays by Dr. Ephraim Cutter appear in one volume, issued by W. A. Kellogg, 9 West 29th St., New York city. The first essay is entitled "The Therapeutical Drinking of Hot Water, its Origin and Use." The second is called "Origin of the Salisbury Plans of Diet in Chronic Diseases, with directions for preparing Beef Pulp." They are instructive to those who would look up these therapeutic devices.

BOOK NOTICES.

Diseases of Women; a Hand-Book for Physicians and Students. By Dr. F. Winckel, etc. Authorized Translation by J. H. Williamson, M. D., with an Introduction by Theophilus Parvin, M. D. Cloth, 8vo., pp. 674. Price, $3.00. Philadelphia. P. Blakiston, Son & Co., 1887.

The name of Winckel is one long familiar to the students of current gynecological literature, and the works of this celebrated teacher have always been popular in Germany. His teaching is practical and his style is direct. Dr. Parvin's suggestion, therefore, that his volume on the diseases of women be presented in an English rendering to the American public, was a good one.

The author's arrangement of his topic is the anatomical one. He begins with the anomalies and diseases of the vulva, proceeding next to those of the vagina, and following with those of the uterus, the fallopian tubes, the ovaries, the pelvic ligaments, and the breasts. In the discussion of them all, he manifests a wide clinical observation, with a markedly conservative tendency. This latter seems to please Dr. Parvin especially, and he takes occasion to emphasize it in his introduction—quite too decidedly, a great many gynecologists will think.

The translation is easy and flowing, and the text is very clearly printed and embellished with a large number of illustrations.

Transactions of the Academy of Medicine in Ireland. Vol. IV. Edited by William Thomson, F. R. C. S. 1 Vol., cloth, 8vo., pp. 463. Dublin, Fannin & Co., 1886.

The volumes issued by the Irish Academy present a valuable series of original papers, carefully prepared and handsomely printed. The contributions are arranged under sections representing medicine, surgery, obstetrics, pathology, state medicine, anatomy, and physiology. Each contains papers well worthy the study of those interested in the progress of these branches.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE PROGRESS OF THE CHOLERA.

We cannot but look with anxiety as spring approaches on the advances of the cholera. It has already secured a foothold on this continent in its southern member, and according to recent advices has crossed the chain of the Andes to appear in the fertile western watershed of Chili, from whose chief seaport, Valparaiso, it may easily be conveyed all along the shore of South America. The active commerce which is in operation conveying the products of the fields and mines of Chili to other shores is a favorable means of spreading the epidemic.

On the east coast Uruguay and the Argentine Republic are affected, the disease having commenced at the important ports of Montevideo and Buenos Ayres. Inland there has been a somewhat wide diffusion into the centre of the Argentine Republic and also as far north as Paraguay. At Montevideo the increase which is taking place is considerable. On the western coast of the continent the disease appears so far to be limited to Santiago. The first spread of cholera to South America is believed to have taken place in connection with a very considerable emigration of Italians to the district of the River Platte; but it is not easy to determine which locality became first affected. The attitude of the several governments concerned is thoroughly characteristic of nations wedded to the quarantine system. Each one begins by denying or minimizing the news as to cholera, and then when all are alike infected they set up a rigid system of quarantine between themselves.

In Europe we do not hear of any cases in France or Italy. During February, however, there was a limited outbreak in northern Bosnia in various villages along the river Save. In fact, there are sufficient threatenings to incite the health officers of our cities to a careful supervision of the sanitary condition of our centers of population.

TRADE JOURNALS, DISGUISED AND UNDISGUISED.

A new, cheap, and effective plan of advertising has lately been discovered, and liberally applied to and upon the medical profession. It is a most admirable plan for the advertiser, because the public to which he addresses himself is quietly hoodwinked into paying for the advertisement!

The simple method to which we refer is for a firm which manufactures some medicinal or dietetic preparation, suddenly to discover a "long-felt want" of the profession

for a new journal, and forthwith to supply the want by establishing a periodical.

The peculiarities of such periodicals is that in the most innocent and casual manner they are always introducing some complimentary allusion to the articles manufactured by the firm which puts up the cash; and never by any chance is anything admitted criticising those articles, or in praise of a competitor.

These journals are usually put at a low price, fifty cents or a dollar a year, and always contain a certain amount of really excellent matter borrowed from other journals or bought by the proprietors. This portion is the make-weight for the concealed advertising, which is liberally and artfully scattered through the pages.

There are dozens of such journals in the United States, for which physicians pay the cost, and which in truth are nothing more than advertising sheets, and their claims to an independent scientific position are preposterous and absurd. One is before us now, which on the title-page professes to be "devoted to investigations into the pathology and physiology of digestion, and the relations of regimen to practical medicine." In reality it is devoted to the advertising of somebody's malt extract, and anybody who sends in a contribution reflecting on that extract would soon learn how much or how little such investigations are accepted in the spirit of science.

All such publications sail under the banner of false pretense; they are dishonest in spirit, and if rightly understood reflect discredit on the house which supports them. Open advocacy is one thing: disguised advertising under the simulation of scientific investigation is another and much less creditable thing. We warn readers against this commercial trick.

PRACTICAL ITEMS.

Dr. Woltering, who is looked upon in Germany as an eminently practical physician, and whose advice has always been found to be based on truthful and correct observations, communicates at times to the medical journals the result of his experience. In the *Allg. Med. Centrl. Zeit.*, December 25, 1886, he reports the following:

He found the hæmostatic action of hydrastis canadensis very prompt in cases of uterine fibro-myoma. In three cases of his, retro-formation and cessation of all bleeding followed the administration of this remedy. On account of its disagreeable taste he prefers to give the drug in the form of pills.

℞. Ext. hydrast. canadens. sicci, ℥iss.
Ext. secal. cornuti,
Ferri reducti, āā gr. xlv.
M. Ft. pil. No. cxx.

Sig.—Every three or four hours from two to five pills, according to the urgency and severity of the hemorrhage. The dry extract (℥iss) is prepared from five drachms fluid extract.

In the hemorrhagic form of endometritis this remedy also proved of great service, while in gastric and pulmonary bleedings—in hæmatemesis and in hæmoptysis—a tablespoonful of ol. terebinthinæ had a more rapid and prompt effect.

W. administers butylchloral in neuralgia of the fifth nerve. One drachm of the remedy is made into forty pills, and two of these are given every hour until the pain has ceased. In cases where this treatment had no effect, the following usually brought about the desired result:

℞. Sod. salicyl., ℥iiss.
Pastæ guaran., gr. lxxv.

M. S.—Half a teaspoonful in coffee every three hours.

This combination can be specially recommended when the neuralgia occurs in persons with a rheumatic tendency.

In most cases from one-sixth to a half grain of morphia—the latter dose only when previous observations in the same individual have demonstrated its safety—hypodermically administered somewhere over the chest, must still be considered the most efficacious remedy in cases of nervous asthma, not as a cure, but for the purpose of giving prompt relief of the dyspnœa. Of late, W. has found that the subcutaneous injection of a little less than one grain (0.05) of cocaine in some cases of nervous asthma is as reliable and effective as the morphia.

THE KNEE PHENOMENON IN LOCOMOTOR ATAXIA.

During the last few years physicians have been in the habit of considering the absence of the patella-reflex as an important diagnostic sign in sclerosis of the posterior columns of the spinal cord, so that when the group of symptoms present admitted a doubt regarding the correctness of the diagnosis of tabes, the absence of the knee-phenomenon generally decided the question in favor of the latter disease.

L. Hirt (*Berl. Klin. Woch.*, 1886, No. 10,) reports three cases of locomotor ataxia, where the patella-reflex was present in undiminished vigor, and one other case where the

same symptom was preserved on one side, while on the other it had disappeared for a year and a half. In the first case, where an autopsy was made, the posterior columns showed the characteristic appearance of sclerosis, macroscopically as well as microscopically. H. believes, in explanation of the peculiarities reported, that the anatomical seat of the patella-reflex, *i. e.*, that part of the cord where this symptom originates, may easily escape the otherwise general sclerotic process of the posterior columns of the cord, just as in some persons there is an absence of all shooting pains, because the posterior roots of spinal nerves are not involved in the morbid lesion, and as also demonstrated by the fact that we have paresis of the sphincter vesicæ in some, and a normal condition of the same muscle in other cases of tabes.

ANGINA PECTORIS.

Angina pectoris happily is a rare disease. There are various neuralgias, often closely resembling this terrible complaint, but they are not accompanied by the decided disturbances of circulation which characterize attacks of true angina pectoris. It is probably due to the rarity of the malady that there still remains some doubt concerning its etiology.

Text-books nowadays teach that whenever the symptoms of angina pectoris accompany any organic lesion, the disease is not angina pectoris. But observations accumulate more and more which prove that true angina pectoris is caused by ossification of the coronary arteries. In the *Aertzl. Int. Bl.*, 1887, No. 1, Dr. J. Wille again reports two cases of this disease, both in favor of the view that ossification of the coronary arteries is responsible for the peculiar attacks of angina pectoris. The autopsy of the first case demonstrated sclerosis of the right arteria coronaria; the second patient possessed only one coronary artery—on the left side—and this was ossified in a high degree. When in consequence of some other accidental circumstances the blood-current in the ossified artery becomes still more impeded, perhaps completely interrupted for the time being, the patient suffering from this condition has the sensation of impending death; a feeling, though, also occurring in some other maladies, which seems to be specially severe in angina. The action of nitrite of amyl would thus find its explanation; and if ossification of the coronary arteries always gives rise to the angina, we cannot be surprised at the uniform fatality of the disease.

Notes and Comments.

Black Tongue.

Dr. R. Balfour Graham thus writes in the *Brit. Med. Jour.*, January 8:

In the *Journal* of October 2 there is an account of a case of the above, and I am desirous to call attention to one that came under my notice about two years ago, while I was assistant to Dr. Lyall, with whose kind permission I publish it. The patient was a rather neurotic woman, about 37 years of age, whose nervousness was, no doubt, added to by a complication of diseases, comprising caries of the dorsal vertebræ, chronic rheumatic arthritis, and chronic Bright's disease; she also had recurrent attacks of an erysipelatous nature on her face, legs, and hands. Her tongue presented over fully half the dorsum a blackness for which I can find no better simile than the appearance of the surface of a dog's nose. The tip and edges were almost free from blackness, as also most of the circumvallate papillæ at the base. To the touch the tongue was hard, but fairly moist. The patient told me that the blackness began with her other ailments, about twelve years ago, and was caused by the administration of large quantities of mercury by the doctor who attended her; that drug was also, she believed, the cause of her losing all her teeth. The latter statement was probably correct. The only remedy that seemed to give the patient any satisfaction (for she claimed to be as good a judge of her condition as any doctor) was a simple stomachic powder containing pulv. rhei five grains, sodæ bicarb. ten grains, and calomel two grains. She said that it was the only powder that ever produced a "moisture" on her skin, which was generally dry and furfuraceous, but its effect on the tongue was not observable. Lotions seemed to have no effect, and scraping simply irritated the mucous membrane. In this case, unlike that recorded by Dr. Stocker, the discoloration never altered in character, and remains unchanged to this day.

Poisoning by Aconite and Belladonna: Treatment by Apomorphine.

On October 8, about 3 a. m., a message came to Dr. W. E. Bradley (*Brit. Med. Jour.*) that J. N., a married man, residing within forty yards of his office, had taken by mistake a dose of liniment, which consisted of equal parts of lin. aconiti and lin. bella-

donnæ. His assistant and himself hastened as quickly as possible to his assistance, when they found him lying across the bed in a state of semi-consciousness. He had not vomited, and was just able with difficulty to drink a small cup of strong coffee before their arrival, but he lapsed almost immediately into a state of unconsciousness. They injected into the arm one-tenth of a grain of apomorphine, and vomiting commenced at once, and continued until his stomach seemed entirely emptied. The pulse soon commenced to beat feebly and irregularly, the extremities became cold, breathing difficult, a cold clammy sweat covered the body, the face became blanched, and the pupils greatly dilated. He had no power of swallowing, so they injected thirty minims of ether, but this had no perceptible influence on the pulse; and, in consequence, a further sixty minims were injected, which caused the heart to beat a little more powerfully. In about half an hour the pulse weakened to such an extent that it could not be felt at the wrist, and the breathing became almost imperceptible. They injected ether to the extent of 120 minims, and this, together with the uninterrupted current over the vagus and vigorous rubbing of the extremities, set the heart beating a little more vigorously. The beat of the heart gradually increased in strength; the extremities, in about three hours, became warm; in five to six hours the surface of the body became slightly sensitive, and he was able to swallow a small quantity of brandy and water. The patient suffered afterwards from a slight attack of inflammation of the left lung, but has now entirely recovered.

The amount of liniment taken in this case (according to the patient's own statement) was about an ounce. His recovery was owing to the fact that they were able to be with him under ten minutes after the poison had been taken, and the quick action of the apomorphine injected.

Glycosuria in Nervous Diseases.

In multiple sclerosis, locomotor ataxia, and in some other affections of the central nervous system, the progress of the disease may be recognized by the presence of sugar in the urine; for the moment glycosuria makes its appearance it would be the most direct evidence of the lesion having reached that part of the floor of the fourth ventricle whose irritation gives rise to the excretion of sugar by the kidneys.

Dr. Edwards (*Revue de Méd.*, 1887, No. 2,) reports an interesting case of that kind: I. M., aged thirty-one, was admitted into the Salpetrière, June, 1886, with the characteristic symptoms of multiple sclerosis. Nine years previously he had suffered from right hemiplegia and aphasia. These latter symptoms soon left him, only to give way two years later to paresis of both extremities. Since that time the paresis gradually increased in severity.

During the further course of the malady some other paralyses appeared; one time the palsy attacked one arm, then again one-half of the body; then aphasia returned. The knee-phenomenon was increased. Intention-tremor and nystagmus were present. In August he was seized with acute hallucinations, which, however, passed off again.

Finally, in November, polyuria, with sugar (180 grms. sugar within twenty-four hours—about 4½ oz.), showed itself, and a short time after, the patient died. The appearance of sugar in these cases always is a bad omen, and invariably denotes a fatal case. It is a symptom present only in the last stages, especially if sugar is abundant.

The Rush Monument.

It would be a worthy testimonial to an eminent member of our profession to erect a monument in Washington to the distinguished Dr. Benjamin Rush, of Pennsylvania, whose active honorable life was crowned by his heroic death on the 19th of April, 1813, in the sixty-eighth year of his age, when, while trying to save other lives, he fell like a soldier on the battle field, a victim of the prevailing epidemic of typhus.

Seventy years ago it was written of him: "Considered in relation to the entire composition of his character—as a practitioner, a teacher, a philosopher, and a writer—Dr. Rush must be acknowledged to have been the most distinguished physician America has produced;" and a later author has said: "The loss of no individual of this country, excepting Washington and Franklin, has been lamented with more universal and pathetic demonstrations of sorrow. As a physician, he has left upon the age in which he lived the impress of his character and genius; in the minds of his countrymen he holds an undisputed preëminence; and amongst foreign nations it is acknowledged that the fame of Sydenham has been rivaled by that of Rush."

The committee to whom has been intrusted the execution of this great work are happy to state that it has met with unquali-

fied approbation from every part of the country, and they accordingly announce that they are now ready to receive subscriptions and donations. Dr. Joseph M. Toner, Washington, D. C., is general treasurer, and for Pennsylvania Dr. J. H. Musser, 3705 Powelton avenue, Philadelphia.

The Pineal Gland.

The dispute concerning the anatomical character, at least as regards the histological elements, of the pineal gland, is not yet concluded. Of late, the view had gained ground more and more that this body was a real gland, with no connection whatever with the brain-tissue proper. Dr. L. Darkschewitsch (*Centrbl. f. d. Med. Wissensch.*, January 1, 1887,) has recently investigated the subject and come to the conclusion that the view above expressed is an erroneous one. By the use of Weigert's hæmatoxylon tincture he has succeeded in demonstrating in the gland numerous nerve-fibres, which originate from the internal capsule, the striæ medullares and Meynert's fasciculus, the tractus opticus and the posterior commissure. Especially those fibres which come from the posterior commissure, seem to be of special importance on account of their intimate connection with the deep origin of the oculomotor nerves. Thus far, however, destruction of the pineal gland has not yet produced any evidence of the important nervous relations of it. Whether D. made the mistake to look upon nerve-fibres proper of the gland—for certainly it must have these—as such establishing connection with deeper parts, we have no means of determining at present; but the subject should be further investigated. The symptoms should be mainly studied which might arise from an excision or other destruction of the gland, for if the latter contain fibres, as D. contends, the removal of the gland should be followed by more remote disturbances.

Prevention of Irritation of the Auditory Meatus.

In the treatment of discharge from the middle ear by insufflation of boracic acid, a good deal of trouble is sometimes caused, especially in frosty weather, by the mixture of discharge and boracic acid causing irritation of the meatus. A good deal can be done to prevent this by drying the meatus well with the cottoned probe before using the acid, so as to prevent deposit of the powder on moist spots, to which it adheres, and to allow its free passage towards the membrane. Dr. Duncan J. Mackenzie (*Brit. Med. Jour.*) has found the following expedient very serviceable. After the powder has been blown in, a small piece of absorbent wool is rolled tightly round the end of the probe, which is then introduced into the meatus, and carried round its circumference, so as to remove all adherent particles. The probe having been withdrawn, the wool is removed, and a fresh piece applied as before; this time, however, it is dipped in eucalyptus and vaseline ointment (one of the oil to seven of vaseline is a good proportion), and the probe is again carried round the meatus. The ear is now closed in the usual way with cotton, medicated or otherwise. When the discharge is not excessive, he thinks the above treatment will be found not only to prevent irritation, but to cure it when it has occurred.

Scopoline.

"This new mydriatic, introduced by Pierd'houy, is," says Dr. Dunn (*Brit. Med. Jour.*), "as far as my experience of it goes, a useful drug. Since the beginning of the current year, I have employed it almost continuously among my out-patients at the West London Hospital, not for the purpose of testing its qualities as a mydriatic, but as a drug to supersede atropine in the treatment of keratitis, corneal ulcers, and iritis. I have found that in the case of troublesome corneal ulcers which had been treated respectively with both atropine and eserine without success, rapid improvement followed the instillation of scopoline. And especially was this good effect shown in cases of severe interstitial keratitis, in which atropine had been previously employed. Again, in rheumatic iritis the use of scopoline was obviously effective in reducing the pain and injection of the globe. Upon no occasion have I seen any conjunctival or other irritation set up by its use, and I have found one grain to the ounce a sufficiently strong solution for my purposes.

"I am disposed to believe that, in addition to its mydriatic power, scopoline is able to effect some control upon the vascular supply of the eye; the drug may be indeed the physiological antithesis of eserine; at present I am engaged upon an inquiry, with Dr. P. S. Abraham, into the physiology and chemistry of the drug, and we hope before long to publish the results."

Croup and Tracheotomy.

It has generally been taught that when

membranous croup attacks a child under two years old no operation should be performed, the reason being that it is considered fatal under these circumstances. But according to the report of Dr. Greffier (*Revue des Mal. del Auf.*, 1886, p. 371,) the tender age of the infant is no longer a contraindication to tracheotomy. There are now on record a number of instances where this operation was performed in the second, and even in the first year of life, and where it resulted in a cure. G. reports the case of an eleven months' old boy, who suffered with membranous croup. Symptoms of suffocation had already commenced when the operation of crico-tracheotomy was performed. Its effect, as usual, was immediate, but also lasting; the infant made an excellent recovery, and was discharged, completely restored, the eighteenth day of its illness. The voice showed but little alteration; it had become slightly hoarse, and assumed the mild metallic sound which seems to be characteristic of all cases that have passed through a successful tracheotomy for membranous croup. If anything can prove the decided difference between the latter disease and laryngeal diphtheria, it is the result of tracheotomy, for this is always fatal when undertaken for the relief of the diphtheritic malady.

On Terpinol.

At a recent meeting of the Paris Academy of Pharmacy, M. Bouchardat made a very interesting communication on *terpinol*. He meant by this name the true chemical already investigated by Armstrong, Tilden, Tanret, and others. He had occasion to prepare at one time several kilogrammes of it. All the writers call it a liquid hydrate, because it has not, so far, been possible to crystallize it. But M. Bouchardat has just succeeded in doing so this winter, not by strong refrigeration, however, but by simply adding to the liquid a few crystals of caoutchine hydrate. The crystals grow with despairing slowness; but still they keep on forming, and after some time the whole becomes a mass of crystals that can be separated from the mother liquors. For the chemical in question he would propose the new name of *terpylenol*, as better adapted chemically, and also to distinguish it from the uncertain substances known by the common appellation of terpinol. He inclines to think terpylenol is very nearly related to caoutchine hydrate, if it be not identical with it. A bottle holding a pound or so of the new crystals was circulated; they are snow-white, one or two inches long, and well shaped. The smell is pleasantly aromatic, in no way recalling turpentine.

New Application of Ether.

The English papers print a report concerning the alleged purchase, on a scale of unprecedented magnitude, of picric acid and sulphuric ether by the French Government. The substances in question are said to be employed in the manufacture of that mysterious explosive known as mélénite, the secret of which is supposed to be in possession of the French War Office. The German daily press has recently confirmed the truth of the reported purchases so far as Germany is concerned, and one paper even named the well-known Berlin "Chemische Fabrik, vormals E. Schering," as being the principal contractor for sulphuric ether. It was added that the managers of the Berlin works, as soon as they became aware of the purpose for which the chemical was required, communicated with the German Government, in order to ascertain whether the continued sale of sulphuric ether to the French War Office was consistent with German interests.

To this communication, it is said, the reply was received that no objection whatever would be raised to the sale of the ether.

Large Doses of Turpentine in Croup.

In a case of membranous croup, Dr. Lewentaner, of Constantinople, administered with his own hands a teaspoonful of the pure oleum terebinthæ, giving after it some warm milk. In a quarter of an hour the labored laryngeal breathing had given way to normal respiration sounds. That night the child slept well and was quite free from the brassy cough which had previously been present. The next morning he was quite lively, and he was found playing with his toys. All trace of false membrane had disappeared from the pharynx, which merely presented a reddened surface. Convalescence was rapid and uninterrupted. The turpentine, however, caused an eruption on the face, trunk, and extremities, having much the same appearance as the rash of measles, but of a brighter red. The spots completely faded in two days, and were followed by no sign of desquamation.

Rotation of Knee-joint.

"On the evening of November 23 I was summoned," says Dr. W. H. Bulteel in the *Brit. Med. Jour.*, "to see J. H., a boy aged

12. He had been 'sky-larking' with some other boys, and was thrown down heavily, apparently when in the act of turning round. The right knee was semi-flexed when seen, and the leg rotated upon it, so that the anterior edge of the tibia looked forwards and outwards, and the outer surface of the fibula backwards and outwards; but the tibia was not dislocated in any other direction, forwards, backwards, or laterally. Reduction was easily effected on acute flexion of the knee, and the leg slipped into position with a creaking sound in the joint. There has been no inflammation or swelling of the joint since. The interest of this case seems to be not so much in the rotation as in its being unaccompanied by dislocation in any of the four possible directions, the previously described cases having, I believe, been almost invariably accompanied by dislocation outwards."

The Biniodide of Mercury as an Emmenagogue.

Dr. C. R. Illingworth writes to the *Lancet* that he has found the red iodide of mercury is a certain and safe emmenagogue. His attention was directed to its virtues quite accidentally some three or four years ago, since which time he has used it successfully in a large number of cases. He prescribes it in the form of a mixture as follows; but he thinks it would act quite as effectually in pills of a quarter of a grain twice a day, or an eighth four times a day:

℞.	Sol. hydrarg. bichlor.,	℥ j.
	Potass. iodid.,	℥ ss.
	Ferri ammon. citrat.,	℥ j.
	Ether. chlorici,	℥ ij.
	Aquam, ad	℥ viij.

Sig.—One tablespoonful three times a day after meals.

Salicylic Eruption.

Burning sensations in the skin, œdema of eyelids, and patches of bluish-red erythema, were noticed by S. Rosenberg to follow the administration of four grammes of salicylate to a sempstress. A bullous eruption appeared on the site of the erythema as the result of continued use of the drug. Three days after the discontinuance of the drug the vesicles dried up. A fresh experimental observation was made, with a similar result. The urine gave a distinct ferric chloride reaction. The inunction of salicyl ointment was followed by burning and red patches on the skin, with blueness of face, and the urine showed the salicyl reaction.

Cocaine as a Poison.

Dr. J. S. Mattison, of Brooklyn, read a paper on "Cocaine Dosage and Cocaine Addiction," before the Kings County Medical Society, February 15, and at its close, a motion made by Dr. Alex. J. C. Skene was unanimously adopted, appointing a committee consisting of the President and Secretary, Drs. Wallace and De Lavergne, and Dr. Mattison, to draft a bill for presentation to the legislature, placing cocaine on the list of poisonous drugs, and to be sold only on physician's prescription.

Treatment of Tuberculosis.

Professor Potain prescribes the following mixture for tuberculous patients:

℞.	Chloride of sodium,	10 grammes.
	Bromide of sodium,	5 grammes.
	Iodide of potassium,	1 gramme.
	Distilled water,	100 grammes.

Sig.—Ingredients to be dissolved, and administered in doses of one teaspoonful in a cup of milk every morning.

News and Miscellany.

Singular Example of Arrest of Development.

A correspondent sends the following notes of a case which came under his notice to the *Brit. Med. Jour.:*

When a student in connection with a maternity hospital in Scotland recently, he was called to attend an out-door midwifery case. The patient was a multipara, and after a short first stage, extending about fifty minutes or an hour, a very powerful uterine contraction brought the child into the world, and this was followed, almost without a pause, by the expulsion of the placenta. The mother believed herself to have reached full time, and the size and weight of the infant were only to a very slight extent less than those of an average child born at full time. The limbs were perfectly developed, and the head and face were normal, except that the right side was possibly a little larger than the left. The thorax and abdomen, however, presented a rather singular appearance. The sternum was totally absent, and the ribs, whilst quite normal behind, only came forward to what should have been the vertical line of the nipple. The integuments of the thorax also stopped short at that line, so that the thoracic cavity was quite open in front. The lungs were collapsed, and occupied the back part of the chest. The heart was in the usual fœtal position, and beating vigorously, and

its action could be thoroughly observed. The diaphragm was incomplete in front in the neighborhood of the middle line. The abdomen was still more patent than the thorax, its integuments coming forward only to the anterior-superior spinous process of the ilium below, and the end of the false ribs above. The chief abdominal viscera were well developed, with the exception of the bladder and the pelvic portions of the sexual apparatus, which were either entirely absent, or so small as to escape detection. The liver was of large size, and its "ligaments" so much lengthened, that it rested between the thighs of the child. The anus was absent, and no traces of external genito-urinary organs were to be seen. The body, with the placenta attached, was laid close to the fire, and for the long period of sixty-five minutes, without any other visible sign of life, the heart continued to pulsate, growing slower and more feeble until at length it stopped. It is much to be regretted that it was found impossible to obtain the body for examination.

Great Men's Dishes.

The *Pall Mall Gazette* says:

"The meals of Charlemagne consisted never of more than four courses, and his favorite dishes were eggs and roast meat, particularly venison, which was served on long spits by his foresters. Luther preferred Torgau beer and hock to all other beverages. As a young man, Melanchthon was very fond of barley soup, and he would often exchange a diet of meat for a bowl of barley soup. Small fish, vegetables, and all kinds of farinaceous food he liked, but large fish and meat he disliked, and he hated all public meals and drinking bouts.

"Torquato Tosso was very fond of preserved fruits and all kinds of fancy sweets. Henry IV. was often ill from eating too many oysters or melons. His favorite drink was Vin d'Arbois. Peter the Great liked nothing better than Limburger cheese. Charles XII., King of Sweden, preferred a piece of bread and butter to anything else. Voltaire, like Frederick the Great and Napoleon I., was very fond of coffee. His favorite food was oat cakes, but he preferred oranges to any other kind of fruit.

"The Dutch lady scholar, A. M. Schurmann, ate spiders as a delicacy. Lessing preferred lentils, and Klopstock, who was a real gourmand, fed on salmon, mushrooms, pastry, and smoked meat. Of vegetables he liked peas best and grapes as dessert, together with a bottle of good claret or hock. Kant retained till old age a preference for pork, all kinds of pulse, and stewed fruit. He devoted three hours a day to his dinner. Schiller was in his youthful days very fond of ham. An old note-book belonging to a Stuttgart restaurant, contains some items about 'Meals for Dr. Schiller in 1782,' from which it appears that, besides a bottle of wine, ham was every day among the dishes on Schiller's table.

"Matthison confessed a preference for peas, beans, and pork; Lord Byron for Chester cheese, with ale or porter; Pope was 'greatly interested' in venison; Jonathan Swift in turbot, and Sir Walter Scott in roast goose."

Suicide by Dynamite.

Some people are dissatisfied with the methods of suicide consecrated by immemorial usage (says the *Medical Press*), and prefer to make use of agents which modern science has placed at their disposal. Dr. Zalaski has recently published two somewhat curious cases of this description. In one, a man, on being arrested for poaching on fish preserves by means of dynamite cartridges, attempted to commit suicide with one of them. He placed it under his chin, but the effect of dynamite explosions being more marked downwards than upwards, the only result was to blow off his right hand, damage the left hand, and mutilate his face. Number two was more successful. He lay down on the ground, placing the cartridge on his chest. After five unsuccessful attempts to light a match, the sixth took fire and exploded the cartridge. The thorax and abdomen were completely emptied of their contents, and the corresponding parts of the vertebral column and ribs were also missing. The other parts of the body were not injured.

A Prescription Number.

The *Shamokin Times* says:

"I was sitting in a drug store one day," said another of the party, "when a gentleman with a very red face and white hair came in, and, taking a little slip of paper from his pocket, said to the prescription clerk: 'George, I wish you would take your files and look back about twenty years and tell what physician signed these numbers.' The files were produced, bound in volumes of 500 prescriptions each, and a list of some dozen or more numbers read off by the anxious inquirer revealed that they were signed

by Dr. D. D. C., who had committed suicide some ten years previous. In a day or two I left the city and was gone for upwards of a year. On my return, happening in at the same drug store, who should come in but the man with the red face and white hair. He took a tremendous drink of Jamaica ginger and departed. Then remembering the queer errand of a year ago, I asked the clerk: 'George, what did General Kellogg want with those old prescription numbers when I was here a year ago?' 'Well, you see, the old fool had been drinking very heavy, and he got it into his head that old Dr. C——n was making nightly pilgrimages from the cemetery and sitting down at his bedside and talking with him. He claims the doctor gave him those prescription numbers to prove that he really was there. It's a little singular how he got hold of those old numbers, but I guess he was on the verge of the tremens. It had one good and one bad effect. He stopped drinking, and turned spiritualist.'"

Bells Strangely Ring Before a Death.

A remarkable coincidence happened recently in Washington at the death of Miss A. R. Duffy, a daughter of Captain O. E. Duffy, the patent attorney. Miss Duffy had lain in a dying condition for several hours, being surrounded by the members of her immediate family. She was conscious to the last and talked calmly with those about her until a moment or two before the end. The nearest watcher had scarcely made the announcement that she was dead when a servant from below entered the room in answer to the summons of the call-bell. No one had rung, and the peculiarity of the circumstance was in the fact that all of the six bells placed in the dining-room and communicating with the different rooms of the house had rung violently at the instant when the death took place. The bells, with one exception, had not rung since Mr. Duffy moved to his present home, the wires connecting them being broken. The affair created a feeling of awe over the household, as no explanation of the mystery has been made.

Congressmen Who Take Electric Shocks.

It is quite "the fad" nowadays for the members to take electricity. An electric apparatus has been fixed up in the engine-room in the basement and daily the members avail themselves of the opportunity to get freshened up. A board, with a tooth-piece of copper, is placed beneath the great belt of the large engine-wheel, and the electricity thus generated is carried off by a wire attached to the board, which is long enough to be grasped by one who sits in a chair near by. The circuit is completed by the person holding the wire grasping a small brass chain attached to the railing around the engine's wheel. The system is thus filled quietly with electricity. The members say it is splendid after they have been out to receptions and suppers all night, or after they have exhausted their brain power by speech-making or listening. A great many members take electricity, and some go to the basement of the Capitol for it every day during the session.

Poisoned by Pills.

A 11-year-old bright little lad, residing in this city, died recently from the effects of strychnine pellets he had eaten the preceding evening, thinking all the time he was swallowing candy. It was at first thought thst the little fellow had purposely taken his own life, but an investigation proved that it was all a mistake. He was sent by his mother to purchase some drugs. A new invoice of drugs had been received, and a package containing about one hundred strychnine pellets, one-thirtieth of a grain each, lay upon a rear counter, They were sugar-coated, and while the druggist's back was turned the boy appropriated a couple of the pills to his own use, and found them to be good. He accordingly confiscated the entire package. The lad was found dead at an early hour in the morning, and all that remained to tell the story was the empty package, labeled "Poison." Whether he swallowed all of the five-score of pills is a mystery.

Liebig's Extract.

Some time since, an action was brought in Brussels against English dealers in extract of meat, to prevent them from using the title of "Baron Liebig's Extract," or from placing a photograph of the late Baron Justus von Liebig on their jars, or in anv way using the name or title of Baron Liebig. The action was brought by the Liebig's Extract of Meat Company, and was successful. The English dealers thereupon took the case into the Court of Appeal. Judgment was given recently, confirming the decision of the Tribunal of Commerce, and condemning the English dealers, who were defendants in the action, to pay damages, and also restraining them from making any further use of Liebig

or Baron Liebig, or of the photograph, this right being declared to be the exclusive property of the Liebig's Extract of Meat Company.

A Switchman's Agonizing Plight.

William Burns, a switchman, at the Eighty-first street yards, Chicago, met with a most terrible and in all probability fatal accident. Recently, while engaged in making up a freight train, his foot was caught in a frog. A freight train was approaching, and Burns, shouting for help, made terrible exertions to extricate himself from his perilous position. At every movement, however, his foot became more firmly wedged, and just before the train reached him, in despair he flung himself backward, breaking his leg at the ankle. As the train rolled by, both his legs were cut off below the knee. He was taken on board the caboose by the trainmen, and, in an unconscious condition, was removed to St. Luke's Hospital, where it was decided to amputate what remained of his limbs below the knees.

Hurt on a Toboggan Slide.

A young girl met with a serious accident at the toboggan slide in Chicago recently. She started to ride down and insisted on guiding the toboggan, claiming to fully understand the art of steering. The sled became unmanageable and went over the side of the chute, carrying its passenger in its fall of thirty feet to the ground. In her descent the girl struck an electric light wire, which tore a frightful gash across her face. A physician took thirty-one stitches in sewing up the wound. Besides this, the unfortunate girl's right arm was fractured in three places, and the flesh was torn from her left arm, exposing the bone. The girl was removed to the County Hospital, where she is at present in a critical condition.

A Valuable Emetic.

A newspaper seller in London fell into a pond, and it was found that he was drunk. An emetic was administered, which had the effect of causing him to vomit four shillings, a sixpence, and a half-penny. He said that he had sold out his stock of newspapers, and had got drunk. He missed his money, and could not understand what had become of it. He therefore threw himself into the water, and now appeared greatly surprised at the singular recovery of his money. He was ordered to find two sureties to be of good behavior for one month.

Therapeutic Notes.

——At the American Institute Fair, New York, last month, the Jerome Kidder Manufacturing Company was awarded a medal of superiority for their electro-medical apparatus.

——Horsford's Acid Phosphate has been tried with gratifying success in London in the treatment of various skin diseases arising from disorders of the digestive tract. It is a valuable preparation, as we can report from personal observation of its effects.

——The "Crystal Pepsin," manufactured by Dr. Carl L. Jensen, continues to find great favor with the profession. We have seen several letters recently, speaking of its effects in the highest terms.

Deaths of Eminent Medical Men Abroad.

The deaths of the following eminent continental medical men have recently been announced:

Dr. Fedele Margary, chief surgeon of the Hospital of San Giovanni Battista in Turin, and editor of the *Archivo di Ortopœdia.* Professor Dr. Halla, the well-known clinical teacher of Prague, in his seventy-fourth year; he had been editor of the *Prager Vierteljahrschrift* since the year 1843. Dr. J. Kalt, one of the most esteemed members of the profession in Bonn; he was a "Sanitätsrath." M. le Dr. Charles Sarazin, formerly agrégé of the old French Faculty of Medicine of Strasburg.

Rabies in Cairo.

We hear from Cairo that there is an epidemic of rabies and hydrophobia there; a good many people have been bitten by rabid dogs, and have died of hydrophobia. Others have been sent to M. Pasteur for treatment. M. Piot, veterinary surgeon in Cairo, is preparing to treat patients by Pasteur's method. It is stated that the introduction of the malady is traced to a terrier hound belonging to a European officer at the Abassieh barracks, which has bitten several native dogs. Some five or six thousand native dogs have been destroyed, but it is believed that many rabid dogs still remain.

Small-Pox in Jamaica.

The small-pox epidemic in Jamaica shows no signs of abatement. Between November 4th and 21st, 1886, 336 cases, of which 37 were fatal, occurred on the island; and of these, 197 cases (35 fatal) were in the town of Kingston. Between November 21st and

December 4th, 541 further cases occurred, of which 49 were fatal. Of these, 152 cases and 17 deaths were in Kingston. Altogether, since the commencement of the epidemic on March 12th last, there have been 2,758 cases and 342 deaths on the island; and out of these, 1,439 cases and 242 deaths have been in Kingston.

Adulteration of Food in Spain.

The Spanish Ministry of the Interior has issued a circular to the governors of the different provinces, calling their attention to the importance of food being sold in a pure and wholesome condition, and directing them to see that the various municipal authorities enforce the laws against all persons of whatever position they may be, who adulterate food, and that their names and the nature of their offences are published in the *Boletin Oficial.*

A Fact in French Country Practice.

A French doctor being asked by a man one day to go a distance to see his sick child, replied that it was too far to walk, and that he had no carriage. "Oh," said the man, "that doesn't matter; I am a livery stable keeper, and will drive you." Some time afterwards the doctor's bill was asked for. It was five francs. The livery stable keeper then presented his bill for the hire of the carriage. It was six francs.

Where Tallow is Appreciated.

The *Savannah News* says:

When a young man in the Aleutian Islands goes to see his sweetheart in the evening, the parents of the girl thoughtfully retire to another compartment of the ice-house, leaving a burning candle with the lovers. Do they let the candle burn? Not much; they promptly blow it out and eat it between them.

A Grateful Patient.

M. Ramon Fernandez, the Mexican Minister in Paris, has informed the Prefect of the Seine that a native of Zacatecas, a State of Mexico, has bequeathed £1060 to a Paris hospital where he was nursed in 1841.

Deaths of Centenarians.

The deaths are reported of a widow in Wetzlau, aged 108, and of the well-known sheikh of the howling dervishes in Constantinople, Alif Baba, aged 110.

Stabbed to Death by his Valet.

Dr. Pebal, professor of chemistry at the Gratz University, was stabbed to death recently by a valet whom he dismissed from his service. The murderer committed suicide by taking poison.

Personals.

—The will of Dr. Edmund C. Rogers, brother of Randolph Rogers, the sculptor, who died at Quincy, Mich., February 19, after leaving a number of bequests to his family and relatives, decrees that the residue of the estate shall be sold and distributed among any six women having families, whose husbands are drunkards.

—Dr. Charles B. Penrose has been appointed a member of the staff of the Orthopædic Hospital.

—Dr. E. Shakespeare has gone to Washington to finish his report on the cholera in Europe.

Items.

—Permanganate of cocaine is announced by M. E. Gesel.

—A journal of hygiene and climatology, called the *Midi Médical,* has been founded at Nice, under the direction of Dr. Onimus.

—Over 5,000 gallons of wine, containing 4½ grains of salicylic acid to the pint, were recntly seized by the New York Board of Health.

—The remains of a Baltimore editor were sold for $10 to a medical college. A live dog is worth more than a dead "lion" in the Monumental City, as well as elsewhere.

—A member of the Nineteenth Century Club, of New York city, believes that the consumption of candy is very injurious to children. The speaker advocates the formation of a candy temperance society.

—A company has been formed in Boston to manufacture "sugarin" from starch. They claim that this substance is sweeter than sugar, and that starch yields ninety-nine per cent. of it when treated according to their secret process.

—The Red Cross Society of Vienna has issued an appeal to all well-to-do persons, requesting them to let the Society know whether, in the event of war, they would be willing to take charge of wounded soldiers. Replies are in each case to specify how many soldiers could be received and cared for gratuitously.

Pallas Syringe."

[From the *London Medical Record.*]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche.

See page 8.

SOLUBLE
PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1054-1256

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant. Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

THE DUTY OF THE STATE TO THE INSANE.*

BY EDWARD M. BRUSH, M. D.,

Senior Assistant Physician, Pennsylvania Hospital for the Insane, Male Department.

The embarrassment of my situation this evening will, I hope, be appreciated, and the crudity of my remarks be excused, when I say that only five days ago was I made aware that a paper was expected from me.

The subject which I have chosen is one to which I have given some thought and investigation, but the time has been too brief to place my ideas in orderly relation to each other, or to gather the scattered host of authorities and references which I might otherwise marshal to my support.

What I have to present, therefore, is thrown out more with the hope of provoking discussion and interest in the subject than with the idea of enlightening any of the members of these two societies, so many of whom have had larger experience, and achieved riper judgment than I have.

There can be no question of the duty of the state to care for its wards in accordance with the best judgment of the time, and to keep pace with the progress which a better knowledge is making for their protection, relief, or, if possible, cure.

Following, as we so closely do in many other things, the English law and practice, it has come to be an accepted fact that those who, from birth or by reason of the accidents and ills of life, are *non compos mentis*, are peculiarly deserving of the watchful guardianship of the state. The earliest English laws had only to do with the estates of these unfortunates, which were the king's prerogative, and out of which their owners were, by legal provision, provided for in accordance with the customs of the time. It came to be observed in time that enactments which had regard only to the estates of the insane did not meet all the requirements of the case, and that the person as well as the estates needed care and custody. Having in view always the "liberty of the subject," which could not be violated without due process of law and for good and sufficient reason, statutes were framed which permitted the restraint of the insane, confining the application at first to those only who were manifestly dangerous to themselves or to others. Gradually the question of confinement for curative purposes came to be considered, and its necessity admitted, until at the present time all civilized countries recognize in some way the legality of commitments to asylums and hospitals of those of the insane who are not of necessity dangerous, but whose detention is justified by the exigencies of treatment.

It is the natural outgrowth of all theories of government which pretend to be paternal in form that the State should afford to its citizen protection, and particularly so "when he is without the use and enjoyment of his mental powers." The means to this end will always be a fair measure of the degree of advancement in civilization attained by the State.

In caring for her insane wards, the State should seek those means which shall best accomplish—

* Read before the Philadelphia Medico-Legal Society.

1. The protection of the insane from themselves and from the cruelty and neglect of others.

2. The protection of its sane citizens from the violence of the insane.

3. The restoration of the insane to a condition of sanity.

I have placed these objects in the order in which they are usually enumerated, and in which the law usually regards them. In the order of their importance they should be reversed, for the restoration of the insane to a condition of sanity implies the accomplishment in the course of its attempt of all the others.

It is, I think, a fact which cannot be controverted that the insane are best cared for and their recovery most surely accomplished in organized hospitals devoted to their special treatment. This is certainly true of those of the indigent and pauper class, who cannot afford to make the arrangements which would otherwise be necessitated; and I feel confident that the hospitals of the future will afford to all classes such accommodations that private care will be as unnecessary as it is often unwise.

To insure the proper treatment of its insane wards, it becomes the duty of the State to make such provisions that all its insane can find ready and proper treatment in its hospitals.

In England and Wales the census of 1880 returns, on the 1st of January, 71,191 lunatics, idiots, and persons of unsound mind. Of these there were in county and borough asylums, hospitals, and district asylums, 44,035 paupers, 3,513 private patients, and 655 criminals; in licensed houses, 1,084 paupers, 3,404 private patients, and 61 criminals; in workhouses (corresponding to our almshouses), 11,991 paupers; residing with relatives and others, 5,980 paupers and 468 private patients.

It will be seen that of the 63,090 pauper insane, 45,219 (or nearly seventy-two per cent.) were in hospitals or licensed houses, and but 11,991 (or about seventeen per cent.) in the insane wards of workhouses, and these are, as required by the Commissions of Lunacy, only of the most quiet and harmless kind. Of the private insane, 7,385 in all, all but 468 were in hospitals or licensed houses.

Let us compare this with the condition of the insane in the State of Pennsylvania, as shown by the United States census of the same year. Of the 8,304 insane in this State, as enumerated in the census of 1880, but thirty-six per cent. were in organized hospitals, eighteen per cent. in almshouses, and forty-six per cent. at home. Massachusetts has sixty per cent. in hospitals, nine per cent. in almshouses, thirty-one per cent. at home. New York, fifty-seven per cent in hospitals, eleven per cent. in almshouses, and thirty-two per cent. at home. Of all the large states, Pennsylvania had the smallest proportion of her insane in hospitals, and the largest in almshouses and at home.

Of all the insane in the United States in 1880, nine per cent. were resident in this state. Of all the insane in hospital but seven per cent. were in Pennsylvania, while sixteen per cent. of all those in almshouses were in Pennsylvania.

Here is a condition of affairs that may well attract attention. I am happy to say that since 1880 a larger number of insane have found accommodation in the hospitals and asylums of this State, but the number is still far below what it should be. According to the second annual report of the Committee on Lunacy of this State, its hospitals afforded accommodation for but 44.5 per cent. of the insane. As the hospital accommodations have not been increased, the percentage at this time is much smaller, owing to the natural increase and accumulation of chronic cases.

Having made suitable provision for the insane, the question of the legal admission and detention of this class is of next importance.

The majority of the enactments in force in the United States and, indeed, in England to-day, appear to have been framed under a most remarkable suspicion that the citizens of the State were in constant menace of being spirited behind the bars of an asylum, and forever disappearing from the view of mankind.

So strong appears to have been the conviction that medical men were ready to conspire to commit their fellow-citizens to asylums for the insane, and that the medical officers of asylums were waiting to aid and abet them, that the law of this State to-day directs that each examiner shall see the patient separately from the other, thus debarring each and the suspected lunatic from the benefits of conjoined examination and consultation.

Hear what an eminent English author, for many years Lord Chancellor's Visitor in Lunacy, says upon this point, which also finds a lodgment in English lunacy law:

"It seems, if one thinks of it, a strange embodiment of jealousy and distrust; for in other instances where the opinions of two or more medical men are required, the opposite

course is taken in order to secure the great advantage of combined observation. When in any other form of disease it is desired to confirm the opinion of one medical man by that of another, what would be thought of the wisdom of a proposal that each man should examine the patient separately? When medical men examine a patient together, they usefully check each other, and are of the greatest mutual assistance in observing correctly and estimating rightly the symptoms of disease, a consideration of the greatest importance in cases of mental disease, whereof the main symptoms are words spoken by the patient, which often convey a different meaning to the minds of different people. If the lunacy laws had not been imbued with distrust of the medical profession, they would never have contained an enactment abrogating all the advantages of medical consultation. Rather would they have enacted that the examination should be a joint one, the opinion concurrent, and the report thereof, or certificate, mutual."

In view of the assertion and implication that the insane are improperly committed, it may be of interest to examine the testimony of the late Lord Shaftesbury, for over forty years the head of the English Lunacy Commission, a man who was eminently entitled to be called the friend of the insane, and whose whole life was spent in improving their condition.

In his testimony before the Parliamentary Committee of 1877 he says, of the one hundred and eighty-five thousand certificates of lunacy that had passed through the hands of the Committee from 1859 to 1877, that he is "quite certain"—I quote his own language—"that, out of the one hundred and eighty-five thousand, there was not one who was not shut up upon good, fair, *prima facie* evidence that he ought to be under care and treatment." Speaking further upon this subject of commitment, he said that, in his opinion, insufficient safeguards were thrown about the liberty of the subject.

If the insane are to be cared for with their recovery in view, every obstacle, as far as practicable, should be removed from their early commitment to asylums and hospitals. Experience has taught that recovery is to be expected only when the case is placed early under treatment.

Sir James Coxe, long the head of the Scotch Committee on Lunacy, a body which has done all in its power to encourage early treatment, testified that every impediment which is thrown in the way of early treatment acts most prejudicially upon the patient by tending to render permanent the aberration. Referring to the experience of the Scotch asylums, whose large percentage of recoveries is due to the fact that early commitment is encouraged and facilitated by the law, he says, citing the example of the Renfrewshire asylums, where the highest percentage of recoveries and the shortest duration of treatment has been attained, that in these particular cases this is brought about by the fact that the directors of the poor can put a patient in the asylum without any difficulty, and that discharge is equally easy.

Dr. Harrington Tuke, before the same Committee of 1877, testified that, in conjunction with the late Dr. Conolly, a man who certainly would not unadvisedly suggest asylum restraint, he had examined the statistics of three asylums with which they had been connected, and found that seventy-seven per cent. of cases treated while the insanity was of less than three months' duration recovered. Those treated at later periods diminished in absolutely geometrical ratio until, after twelve months' duration, it was something like twelve per cent. of recoveries.

These statistics bear out some calculations of my own, made at the State Lunatic Asylum at Utica five years ago, and published in the Asylum reports. Of the admissions to that institution for ten years, aggregating four thousand one hundred and twenty-nine insane persons, thirty-two and a half per cent. recovered. Of those insane a year and over, but twelve and one-third per cent. recovered; while of the entire number insane under twelve months, forty-four per cent. recovered.

At this point reference may be proper to the unfortunate result of agitation concerning lunacy matters and the suspicion cast upon asylums and their management by newspapers, legislative committees, etc.

In New York State, the year 1878 marks the commencement of a series of most malignant attacks upon the asylum-system of the State, resulting in no less than five legislative inquiries, which have, I am happy to say, resulted in a vindication of the asylum officials and the lunacy laws of the State from the charge of improper commitment to asylums, or unjust confinement or treatment therein.

The results, as concerns the unfortunate insane, were not so happy. For seven years, (1872 to 1878, both inclusive) the average percentage of cases admitted to the Asylum at Utica who were insane a year or more on reception was thirty-three and a third. In

1879 it rose to thirty-five and one-half, and in 1884 it reached fifty-one and six-tenths, the average for the second period of seven years (1879–1885) being forty-five per cent. of practically chronic cases.

The second, third, and fourth reports of the Committee of Lunacy of this State will show that from forty-two per cent., or a little over two-fifths of the admissions, for the past three years, to all the organized hospitals and asylums of the State, seventy-three and two-thirds, or nearly three-fourths of all the recoveries were drawn.

These reports will also show that fifty-eight per cent. of the cases admitted to the hospitals and asylums were chronic cases.

What is the remedy? Primarily, it seems to me, the creation of a public sentiment in favor of hospitals and asylums. The removal as far as possible of the feeling of distrust and suspicion which now surrounds the subject is necessary to induce the friends of the insane to take advantage of the facilities offered them for treatment.

It is, of course, implied that the State shall furnish sufficient accommodations for its insane before asking its citizens to take advantage of them.

One great obstacle which lies in the path of early asylum treatment is the objection which physicians have against signing certificates of insanity.

The law places upon them the onus of saying not only that the person examined is insane, but that he is a proper case for confinement. They are not protected in any way against the annoyance of suit for damages brought by unrecovered lunatics before ignorant and prejudiced juries. Many physicians in general practice, moreover, feel themselves without sufficient training and experience in the diagnosis of insanity to be able or willing, in the very earliest stages of the disease, to take the responsibility of diagnosis and certification. To obviate this, all medical schools should make instruction upon insanity a by no means unimportant part of their medical course, and attendance necessary to graduation. I speak with all due respect for the knowledge and diagnostic acumen of my medical brethren in general practice when I say that of one single form of insanity, one that is singularly regular and characteristic in its manifestations, I have not known a single case out of over two hundred and fifty to be recognized before commitment. I refer to paresis. The mental disturbance was appreciated, as evinced by the certificate, but the peculiar form wholly unrecognized.

The fault was not with the physicians. They had never had occasion or opportunity to receive instruction in these cases.

Another element which is active in preventing early asylum-treatment is the indisposition of poor-relief officers, overseers, and others, to grant orders of admission until some overt act or threatened violence makes detention necessary; and too often in such cases even the wish to stand well with an unthinking constituency by a show of economy results in the incarceration of acute cases in almshouses. The law should make such action a misdemeanor.

In the State of New York, except in the counties of Kings, New York, and Monroe, there is no place except a State asylum where a case of acute insanity requiring public relief can be legally detained.

As far as proper care is concerned, the pauper seems in the State of Pennsylvania to have the advantage. Persons who are able to pay the low rates of three and four dollars weekly are compelled to depend upon the charity of the incorporated hospital, as in their present crowded condition the State asylums cannot receive them.

The provision of the New York lunacy law in regard to the indigent insane not paupers might, it seems to me, be well imitated.

I am informed that the necessary exclusion of these cases has resulted in part in the at present low percentage of recoveries in the hospitals of this State.

It seems a crying wrong that a small taxpayer who has assisted for years in supporting the hospitals of the State must, when becoming insane, be refused the benefit of treatment because his place is occupied by a pauper, of whose recovery, in four cases out of five, there is no expectation.

In the thirty-eighth annual report of the Commissioners in Lunacy for Scotland reference is made to exactly this condition of things, which was found to exist in one of the royal asylums (institutions corresponding somewhat with our State asylums). The Commissioners say of this asylum; at present the public are suffering by the presence in the asylum of pauper patients, who might, as they point out, be as well provided for elsewhere, being quiet chronic cases. As a consequence, twenty-seven private patients at low rates were refused. At the time of the visit (of the Commissioners) two letters applying for admission were seen, one of which from a mechanic points out that, so far as he can see, but two classes were provided for, the very rich and the very poor. The Com-

missioners very emphatically animadvert upon this condition of affairs.

The State owes a duty to all classes of her citizens to so provide that they may feel assured that in the event of becoming insane they shall be properly cared for.

Not by any means the least of the duties of the State is to provide, by Commissioners or otherwise, such a system of inspection and visitation of all places where the insane are confined that their friends shall be afforded a means of satisfying themselves of the proper conduct of such places.

Such a Commission is or should be an educator of the people—a bulwark on the one hand against unjust charges concerning asylum and hospital management, and on the other against the improper care and custody of the insane.

Imbued with a right spirit, they are strong factors in the establishment and maintenance of a proper system of hospital care, as witness the course of the English and Scotch Commissioners, who have been a real help to asylum physicians instead of captious critics, and who have by their course aided very materially in promoting the prompt and proper care of the insane. So strong has become the opinion of the English Commissioners in favor of early treatment that when it was recently proposed to throw, by an amendment of the law, increased difficulties in the way of early commitments, the chairman of the Commission resigned rather than by retaining office seem to sanction such a change.

The Lunacy Committee of this State is, I believe, endeavoring to emulate the example of its English prototype. Under our more recent laws, which in some respects are not harmonious in all their relations, and with few American precedents to guide it, and an incomplete asylum system to work with, the Committee may not in all things accomplish at once what might be desired. Its hands should be sustained, however, and time and wider experience may be trusted to work much good.

THE RHUS GLABRUM—A REMEDY FOR STOMATITIS.

BY HIRAM CORSON, M. D.,

Of Conshohocken, Pa.

Your readers may not consider a paper on this subject of sufficient importance to occupy their attention, inasmuch as it is often a very trifling affection—"thrush," "baby's sore mouth," etc.—but as the term is used by authors to embrace not only these trifling affections, but others much more serious and ofttimes fatal, and as the remedy which I have often used is a very safe one—by that I mean not poisonous—even in the mouths of little children, they will probably be willing to read what can be said in its favor. I am, too, impelled to offer it because only a few years ago a medical friend lost a loved child of tender age from stomatitis, which was cause of great sorrow to the parents; and also because Professor Thomas Spencer, of New York State, was, when in active practice, thirty years or more ago, prosecuted for malpractice, charged with having salivated a child and causing its death while treating it for cholera infantum, though he had not used a grain of mercury in the case.

The first notice I ever saw of the use of sumach was in the May number of the *American Journal of the Medical Sciences* in 1829, in a paper by Dr. Wm. Fahnestock entitled "On the Rhus Glabrum as a Remedy for Ptyalism." I fancy your readers are about to say, What has a remedy for ptyalism to do with the treatment of stomatitis? or, rather, is there such similarity in cause or morbid condition that the remedy for one would be likely to benefit the other?

What an opening there is here now to talk about germs; about every grade of stomatitis being caused by a different kind of germ, and that the remedy for the affection must be a germicide, and to descant learnedly on ptyalism as the result of a weakening of the system by the use of mercury, so that the germs, which were lying in the mouth in countless numbers, unable to prey on its structures while in full health, were loosed from their thraldom, enabled to multiply, and began their ravages on the tissues! But I am not fitted for this opportunity, so will return and speak of my subject as though germs had never been heard of. Dr. Fahnestock's "first case was a patient who had been treated with mercury internally and externally for typhoid pneumonia, and which affected the system to a most distressing degree." So it seems there was typhoid pneumonia fifty years—nearly sixty years—ago, when, in the opinion of our present medical teachers, the human system was strong, and patients could bear depletion not allowable now. Professor F. continues: "The face and eyes were very much swollen, the tongue enlarged and protruded, the internal surface of the mouth denuded, and the fauces in ulcers. A luke-warm gargle of the inner bark of the root of the Pennsylvania sumach was ordered to be

used every fifteen minutes, and mucilaginous drinks enjoined; relief was soon experienced, and in a few days the irritation was entirely removed."

Case 2. "A girl 9 years old, profusely salivated when ill with remittent fever, and which resisted all the irritating compounds of borax, myrrh, etc., and continued until it had effected anchylosis of the jaw, extensive caries of the upper maxillary bone and sloughing of the cheek; then put under the care of another physician, who, after a time, abandoned the case in despair.

"She was then directed to a notorious panacea shop of this city, and dosed with half a dozen bottles of the celebrated nostrum, with no other effect than increasing the irritation and extending the sufferings.

"We were then asked to visit the child, and found her with jaw perfectly fixed, the angle of the mouth sloughed away, the superior maxillary bone of one side carious, and discharging from four to six ounces of the most fetid sanies every 24 hours, which excoriated the cheeks and rendered her extremely offensive to all attendants.

"We recommended to her as the only prospect of relief to submit to an operation, provided healthy action could first be produced in the parts, which we anticipated from the *correcting qualities* of the sumach. She was immediately put under treatment, laxative and mucilaginous drinks ordered, and the gargle of the sumach used every half hour. In the course of a week or ten days the morbid action was changed, and the parts put on a healthy appearance.

"The operation was then performed, in which we removed the whole alveolar process of the affected side; the gums united most gently, the ulcer of the cheek healed up, and the patient recovered rapidly and has remained perfectly well." (The operation was performed December, 1825.)

I may add to this that I have known the patient intimately for more than fifty years, and though her face is somewhat deformed, she is a healthy woman, the mother of healthy children, and now about 75 years of age.

Having thus shown its value as a remedy in ptyalism, which seems to have kinship with stomatitis, it is necessary to show how nearly alike are the symptoms, and that the sumach is as efficient in the one disease as in the other.

Dr. Joseph Parrish, half a century ago, in lecturing to his private pupils, used to speak to them when treating of diseases of the mouth, of a severe form of stomatitis, as "A disease resembling the effect of mercury," and Dr. Jesse Young, an eminent practitioner, in an article "On the Gangrenous Sore Mouth of Children," published in the *American Journal* for May, 1831, thus refers to the name of the disease given by Dr. Parrish: "I frequently see descriptions of a disease under the names cancrum oris, gangrenous sore mouth, humid gangrene of the lips, gangrenous erosion of the cheek, etc., etc., but there cannot be a more practical name, or one that conveys a more accurate idea of its appearance, than that applied to it by Dr. Parrish."

Dr. Young did not regard this disease as a trifling one; he speaks of it as "being frequently fatal under all the different modes of practice resorted to by different practitioners, and that no means have been heretofore generally successful, with the single exception of sulphas cupri."

His desire was to add another remedy to the list, and for that purpose he wrote his essay. Allow me to quote a portion of it, to show how greatly his case resembled Dr. Fahnestock's, and yet the one was stomatitis, a disease resembling the effects of mercury, the other the mercurial disease itself. In June, 1824, was called to a child four years and two months old, sick a week, despite efforts to cure it, and steadily getting worse. "On visiting him it was with difficulty I could be convinced that the child was not laboring under a severe mercurial salivation, there being several sores in the roof of his mouth and in the cheeks, which had exactly the appearance of mercurial sores; the saliva flowed constantly from his mouth, and his breath exhaled an uncommonly fetid odor. On being assured that he had taken no mercury, and that it was impossible for him to have obtained it, I gave up the idea of mercury, and concluded that it must depend on an unfavorable state of the stomach and intestines." At that time Dr. Young had not heard of the value of sulph. cupri. He began treatment of the child June 13; June 14 and 15 it grew steadily worse; on the 16th he wrote: "The sores look darker than yesterday, and I began seriously to apprehend a fatal result, particularly so, as I heard this morning of the death of a child in the neighborhood from what was said to be the same disease. Almost in despair of curing, I ordered a gargle or wash of eight grains of deuto-chloride of mercury in an ounce of water; the sores to be cautiously but accurately touched three times a day by means of a swab; and a tablespoonful of the decoction of Peruvian bark every four hours to be taken.

"By the 20th the sores had all sloughed, some of the small ones had healed entirely, and the larger ones had a healthy florid appearance. Two of the other children were attacked, but not the least difficulty was found in curing them by the same means. Since then I have seen about thirteen cases, all readily cured by the same treatment." He adds: "Here, I would be understood as distinguishing between the disease in question and the aphthous sore mouth of children, so common, and which mothers generally manage themselves."

My object in quoting so largely from the physicians named was to show that these three careful observers could not distinguish between what is considered a dangerous stomatitis and a bad case of mercurial salivation, which in those days they not infrequently encountered. I have had both kinds of cases, from the mildest to the severest, and in the management of them have used the gargle or wash of the inner bark of the sumach, with excellent results. I had seen some cases of severe salivation before I saw Dr. Fahnestock's recommendation of the sumach in 1829; even while a student in the summer of 1826–27, when intermittent and bilious fevers were in nearly every home along the rivers Delaware and Schuylkill, and calomel was the common purgative and used in all affections, mercurial salivation was of course frequently met with, and at that time, a dose of one drachm of calomel prescribed for me after five calomel and jalap pills had failed to do their work, salivated me severely, and showed me that the remedies for the relief of salivation were not very efficient. Before going further allow me to say here, in defence of the physicians of that time, that this free use of mercury was not an unmitigated evil. It was indeed life and health to many, many people; for as soon as ptyalism was effected, attacks of fever of the most violent kind were at once shorn of their virulence, and convalescence commenced. So it was in my own case; so it proved to be in many cases of pneumonia, pleurisy, and some other inflammatory affections. It is well known to aged practitioners now living that, in dropsies and some other diseases where mercurials are of themselves not able to cure, the effect of ptyalism is to render the action of other remedies more efficient. Excuse the digression. During my first year of practice a woman sent to a drug store and got ten grains of calomel, and though it purged her well, without unusual delay, she was fearfully salivated. For weeks she was compelled to lie in bed on her side, so that the copious secretion of saliva could run from her mouth into a basin instead of going down her throat. The various means then in vogue to check the flow and heal the ulcers were persistently and almost unavailingly tried, and she continued to suffer on for weeks. This caused me to be very timid about the use of calomel; but after the sumach proved to be so efficient in the hands of Dr. F., the fear of ptyalism greatly subsided.

In December, 1836, I was called to attend a sea captain who had been badly ptyalized in Cuba when under treatment for "liver complaint." When I saw him at the house of his friend here, he requested me not to use any form of mercury when treating him, because he had suffered so greatly on the former occasion, and so long that he was compelled to go to England for change of climate in order to get well. I spoke to him of the curative power of the sumach, but he would not yield; so I did the best I knew for a few days without the mercury, and without any benefit to him, and then cautiously gave him some; fearing that I might have trouble with him, knowing full well that when a person has once been ptyalized by mercury, a very little will produce it again. On going into his room a few days later, I at once discovered the mercurial odor, and at the same moment he began to upbraid me in choice seafaring terms for what I had done. He was at once given the sumach infusion, or decoction rather, with which he washed his mouth thoroughly and often, and was soon well and delighted with the remedy. He also took at the same time the infusion of Peruvian bark, as directed by Parrish and used by Dr. Young.

So year after year, as cases occurred, I treated them—the mild and the severe, the baby's sore mouth, and all the grades up to the gangrenous sore mouth—with the sumach as the local application, in many of them using nothing internally beyond the mouth, except in one case.

On one occasion in a violent, rapid cancrum oris, which had so far advanced when I was called that it seemed as though the disease would soon pass through the cheek, I feared to delay, feared the sumach would of itself be too slow, so swabbed out the gangrenous ulcer with nitric acid, and followed that with the sumach mucilage, with the most saving result.

It would be quite useless to call up the numerous cases which have presented themselves in a half century's daily practice, in all of which I used the sumach mucilage

with comfort to the patient and satisfaction to myself, but I may mention a single case which occurred. In August, 1881, was called to see a granddaughter of John Downs, a healthy Scotchman, living at Spring Mill, who was suffering greatly with ulcers on the cheeks, roof of the mouth, and on the gums and side of the tongue, with a copious secretion and most offensive breath issuing from the mouth. The little thing was complaining heavily, and what they had put into her mouth for relief had so hurt her that she had a fear of everything offered to her. As the sumach was abundant, not fifty yards from the house, among the hornblende boulders on the hill, it was soon dug and prepared for use. It was so mild as to be, instead of painful, most comfortable, and was used without other remedies save a mild cathartic or two. I began on the 12th; in recording my last visit on the 20th I find this record: "The sumach was a success." She was not only well, but from the hour she began it she was comfortable, a matter of some moment to a child only a few years old.

What else shall I say? That I had a dread of sulph. of copper and the bichloride of mercury. It is difficult to use them with children and have the parents to use them in our absence without danger of their swallowing the secretion, carrying with it some of the poison, especially when used as the corrosive sublimate was—eight grains to the ounce of water. With the sumach I felt safe. The root of the sumach has a thin outer mahogany-colored bark, thin as blotting-paper, which, when the root is freshly dug, is readily scraped off with the back of a table-knife, but if left until it dries can hardly be removed without cutting it off; under that is a thick, succulent, white bark, easily shaved from the wood. This, when dried, keeps well; this put into a clean white bowl and covered with boiling water, and even boiled, soon becomes a mucilage without taste or smell, and is ready for use. I generally procure it in the fall, and have it carefully dried.

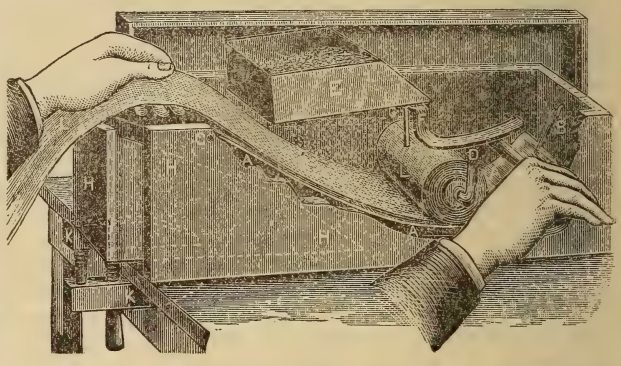
Here I ought to stop, though feeling how pleasant it would be to me to tell your readers how valuable many of our indigenous plants were to us who practiced long, long ago. This theme may serve me in times yet to come. Vain hope! they will never come to me.

A NEW APPARATUS FOR PREPARING DRY GYPSUM BANDAGES.*

BY H. AUGUSTUS WILSON, M. D.,

Of Philadelphia.

Rolling the dry plaster-of-Paris bandages by hand, the method usually in use, is unsatisfactory, and under the most favorable circumstances a dirty process. It was to avoid the inconveniences and irregularities of that method that I devised this apparatus, which I have had made by A. G. Gefvert, the orthopædic apparatus manufacturer.



It consists of an ordinary box-bandage roller, with the addition of the following: A movable bottom, A, A, A, held in contact with the outermost layer of the bandage, as it is rolled, by a rubber band B, and at the other end by a hinge-joint C. Upon this movable bottom, and just in front of the crank, is a flood-gate or distributor, not shown in the illustration, which equalizes the distribution of the plaster and presses it into the bandage from above, while the movable bottom prevents the gypsum from passing through the meshes. The proper tension is applied by two rubber bands.

A hopper, E, is provided with an arm, F, bent in such a manner as to be raised by the crank at each half turn, and upon being released it falls, throwing down a quantity of the powder upon the bandage in front of the distributor. A compartment, H, H, H, occupying the otherwise waste space under the movable botton, is utilized as a receptacle in which may be kept the gypsum when the apparatus is not in use.

A scoop accompanies the apparatus with which to take gypsum from the compartment and fill the hopper. The entire affair can be securely held to a table by clamp, K. Elastic bands are used for springs, because they are inexpensive and can be very readily replaced when worn out.

* Read before the Philadelphia County Medical Society.

The method of using is, first to pass the end of the bandage to be rolled over the movable bottom, under the distributor, and attach to the crank. The hopper is now to be placed in position and, by means of the scoop, filled with a sufficient quantity of gypsum. While the crank is turned with the right hand the left guides the bandage, which may be watched, over the hopper, as it is being rolled.

The bent arm of the hopper is so arranged that the fall of the hopper may be sudden or gradual, and upon this depends the quantity of powder discharged. When the crank is turned very slowly the hopper is raised slowly and descends with the motion of the crank, and scarcely any gypsum is precipitated, and, of course, the converse follows. This being clearly understood, a very slight experience will enable any one to control the action of the hopper with the crank.

When a bandage is finished, the crank is withdrawn sufficiently to disengage it from the bent arm of the hopper, and while the left hand holds the bandage a quick reverse turn of the crank enables it to be easily withdrawn. The gypsum remaining on the movable bottom is now discharged into the compartment by placing the hopper to one side, detaching the spring, B, and raising that end.

The apparatus is applicable to the rolling of the ordinary surgical bandage by detaching the rubber spring, B, thus allowing the movable bottom to drop out of the way. It prepares the dry gypsum bandages evenly and quickly. It is very simple in its construction and action. It cannot get out of order, except by breaking of the rubber bands. It is inexpensive.

Possessing these advantages, I hope it will be of service and facilitate the preparation of the dry gypsum bandages in the hands of other physicians, as it undoubtedly has in mine.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

Stated meeting, January 17, 1887. The President, Edmund J. Doering, M. D., in the chair.

OFFICIAL REPORT.

Dr. Lyman Ware read a paper entitled

A Clinical Study of Glaucoma.

The author briefly referred to the history, pathology, and etiology of glaucoma, and expressed his belief in the curative power of Von Graefe's operation of iridectomy. Unmistakable symptoms of glaucoma are supra-orbital and ciliary neuralgia, increased ocular tension, periodic diminution of vision, the appearance of a halo around artificial lights, a sluggish and widely dilated pupil, and a shallow anterior chamber. Although increased tension may be associated with other diseases of the eye, its presence should always lead to a critical examination. Several cases were detailed: Mrs. M., aged fifty, while riding in an open street-car, contracted a severe cold, which was followed by neuralgia over both eyes. The pain was so intense that at times she was delirious. Her weight was reduced from 110 to 80 pounds. She became entirely blind. On account of the eye being small and deeply set and the anterior chamber very shallow, sclerotomy was advised and performed. This gave immediate relief, but the pain returned again in a few days. When Dr. Ware saw the case the anterior chamber was almost obliterated, the glaucomatous lens pressed the iris forward until it came in contact with the cornea. With a Von Graefe cataract knife a free sclero-corneal incision was made and a portion of the iris excised, and the lens removed from both eyes. The pain greatly subsided, but the sight was irrecoverably lost. Another case was a man, aged fifty-two years, who complained of having had pain in and over the the left eye for five or six months, and had seen the halo about street lights. On examination, tension was found increased, vision diminished one-half. Some months later iridectomy was performed, and a solution of eserine (4 grs. to the oz.) instilled every four hours into the other eye. Pain was at once relieved, and all symptoms of glaucoma rapidly disappeared. Mrs. M., aged forty-five, had frequent attacks of neuralgia and noticed defective vision in the left eye six months before coming under observation. Tension was found much increased; she had seen halo about artificial lights for eight or ten months. Distant objects could be clearly perceived by right eye. Iridectomy was performed on the left eye with a view of abating the pain and preserving the vision of the right eye. The relief from pain was great, vision of right eye fully restored, and left eye much improved.

Dr. E. E. Holmes reported

A Case of Foreign Body in the Anterior Chamber.

This case was of special interest to me on account of the difficult diagnosis and the

difficulty attending the removal of the foreign body. The doubt regarding the diagnosis arose from the fact that there was a small central perforation of the cornea. Below this, and not connected with it, was a fine greyish line extending downward and inward (right eye), apparently in the substance of the cornea, fairly into the angle of the iris and cornea. This resembled the channels left after the removal of fine slivers of grain stalk, which are sometimes thrown into the cornea obliquely from threshing-machines. The patient explained the accident as follows: He was setting a machine punch so the punch would accurately fit the die. The power was applied, when the punch did not accurately correspond to the die. At the same instant something entered the patient's eye. He came to my house twenty-four hours after the accident, with the eye slightly red, but not painful. I prescribed atropine and sent him to the hospital. The next morning the pupil was round and fully dilated. The media were all clear. I felt great anxiety in regard to the case, but inasmuch as during five days there were no symptoms of inflammation along the supposed track in the cornea, I finally became convinced that there was a fine splinter in the anterior chamber, in close contact with the cornea.

I made quite a long incision through the lower border of the cornea, the knife touching and moving the piece of steel. I endeavored by means of a fine forceps to seize the lower part of the steel and disengage the point from the tissues at the angle of the iris and cornea by carrying the steel farther towards the pupil. This was found to be impracticable, since the lower end of the piece was firmly held by the tissues. I used all the violence I considered warrantable. As the anterior chamber was without aqueous humor, there was some difficulty in further procedure without violence to the lens or iris. I consequently extended the wound in the cornea upward, so the upper end would correspond with the upper end of the steel. This end was easily seized, and with considerable force withdrawn. The splinter was three-sixteenths of an inch in length. Eserine at first, then atropine with antiseptic dressings were applied with great care. There was no reaction, the patient recovering perfect sight, except as far as there was dimness from the central cicatrix in the cornea. Vision was good five weeks after the patient had returned home. I must confess the almost V-shaped incision in the lower border of the cornea did not please me.

Dr. Holmes also reported

A Case of Intra-ocular Tumor.

This tumor, filling the sclerotic, is a sarcoma of the choroid. The patient, a man 62 years of age, had been under the observation of several specialists during the past year, but could not give me a definite expression of their opinion. When he came to me, a few days ago, the cornea was perforated and presented a staphylomatous projection of the growth. For a year there has been pain and, for the last six months very great pain. The tissues of the orbit around the globe were greatly swollen, but not indurated. In enucleating the eye I expected to find the sclerotic destroyed posteriorly and the orbital tissues invaded. The enucleation, however, was performed as easily as in ordinary cases. The optic nerve is seen to be enlarged several millimetres beyond the sclerotic. The swelling in the orbit was caused by nodules of fat filled with numerous blood-vessels. Dr. Ochsner pronounces the tumor to be a small round-celled sarcoma, with very little pigment. The nodules of fat are free from sarcoma cells. This class of tumors, if removed early, are not very liable to return in the orbit. They may, however, re-appear, especially in the liver or other internal organs. They must, consequently, be regarded as quite malignant.

Dr. Boerne Bettman read a paper on the

Connection between Ocular and Nasal Diseases.

The author thought that numerous pathological conditions of the eyes and lids are attributable to normal changes in the nose, and that in these cases treatment of the ocular organs alone will fail to alleviate the trouble. After referring to Hack's monograph on the subject, Dr. Bettman detailed several cases in substantiation of his theory: A boy of 10 applied for treatment of epiphora of both eyes. The eyes were constantly weeping. An examination of the nose revealed an extensive swelling of the anterior portion of both turbinated bones. When these parts were touched with the probe profuse lachrymation was induced, and a light thrown into the eye by means of the ophthalmoscope produced violent sneezing. A deep incision was made in the swelling with a knife electrode, and a flat burner was also employed. The slough was completely thrown off in fourteen days and the boy cured in one month, the eyes receiving no treatment. Polypi of the nose have been found to produce secondary affections of the eye. Hermann S. was prevented from fol-

lowing his trade of a cabinet-maker on account of the excessive flow of tears; he also complained of pain in the eyes. Polypi were removed from the middle turbinated bone with the Jarvis snare and a cure effected. E. B., aged 16, was extremely sensitive to light, and the eyes were both bathed in tears. Each time the eyes were exposed to a glare of light she sneezed violently. There was Hack's swelling in both nostrils. Two pledgets of cotton were soaked in a 5 per cent. solution of cocaine, and allowed to remain five minutes at a time. There was an immediate effect, and in three-quarters of an hour she was able to bear the light. The patient refused cauterization, and employs cocaine to avert photophobia. The majority of cases coming under Dr. Bettman's observation have been treated by applications of the galvano-cautery to the nasal membrane. The applications restricted to the anterior end of the turbinated bone frequently fail to give relief. It has been found that a sensitive area exists at the posterior end of the inferior turbinated bone, and also at the anterior part of the nasal cavity, in the angle forming the boundary of the vestibule. In conclusion, the author thought oculists should always subject the nose to a thorough examination when seeking the source of ocular complaints.

Dr. H. M. Starky read a paper entitled

Some Modifications in the Treatment of Stricture of the Nasal Duct.

The author said that about 1883 the Western Repository Company made a lachrymal bougie of medicated gelatine of such elasticity that it could easily be passed into the nasal duct. It was less painful than a metal probe, and its slow solubility kept the mucous membrane at the point of stricture distended so that it could be acted upon by the medicine from thirty to sixty minutes. He thought results showed the use of electrolysis in these cases to be often unsatisfactory. The object to be attained is to restore the diseased parts to as nearly a normal condition as possible, and the most satisfactory treatment is by using injections more and probing less frequently. The author determined to try the effect of probing the punctum without slitting the canaliculus, followed by astringent injections over the inflamed surface. This treatment proved entirely satisfactory, and in about five weeks a patient went to his home in another State with apparently perfect recovery, and no destruction of tissue.

The following case was given as illustrating the author's method of treatment: Mrs. L. suffered from lachrymation of each eye for two years. There was severe lachrymal conjunctivitis of the right eye, the punctum being contracted one-half. On dilating the right punctum a No. 2 probe could be passed without difficulty, but the whole interior of the nasal duct had the peculiar velvety feeling that is caused by thick villous mucous membrane. The same condition, in less degree, was found on the left side. Treatment was commenced by applying a weak astringent and washing out the lachrymal canals thoroughly each day with boric acid lotion, followed by a weak astringent. Once a week a probe was passed through the dilated punctum down to the nares, using a larger probe each time until No. 7 was reached. The result was satisfactory, and in six weeks the patient returned home apparently well.

Dr. W. Franklin Coleman read a paper on

Sympathetic Ophthalmia.

Disease in the sympathetic eye generally occurs when there has been a wound or operation in the dangerous zone of the diseased eye. Becker, in 1875, collected twenty-two cases of sympathetic ophthalmia from cataract operations, foreign bodies lodging in the eye, and degeneration of a lost eye, or other causes. Dr. Coleman read in detail the clinical history of the disease, and enumerated the causes, histories, and results of the treatment of a large number of cases. In regard to treatment, he advised as per the following:

CONDITION DISEASED EYE.	CONDITION SYMPATHETIC EYE.	TREATMENT.
Blindness.	Normal.	Enucleation in unintelligent and children.
Blindness.	Sympathetic irritation.	Enucleate.
Blindness.	Sympathetic inflammation.	Enucleation not often advisable.
More or less vision.	Normal.	Do not enucleate generally.
More or less vision.	Sympathetic irritation.	Better enucleate.
More or less vision.	Sympathetic inflammation.	Do not enucleate.
Acute ophthalmitis.	Normal.	Never enucleate.
Acute ophthalmitis.	Sympathetic irritation.	Puncture and foment diseased eye, then enucleate.
Acute ophthalmitis.	Sympathetic ophthalmitis.	Treat ophthalmitis, then enucleate.

Dr. F. C. Hotz said: "I think the theory of the author in regard to the closing of Schlemm's canal and the approximation of

the iris to the cornea interfering with filtration cannot account for glaucoma. Pathological anatomy has so far failed to find the cause, and we have to rely on clinical studies to build up a theory which will account not for the late stage, the fully developed glaucoma, where the sight of the eye has been permanently destroyed by the disease, and which the pathologist gets from the oculist after enucleation, but for the first stage, the premonitory symptoms before it becomes an acute attack; a stage which the pathologist has not yet investigated with his microscope. At that stage who can say certainly what glaucoma is? It is probable that various causes lead to the same result. I believe that the agglutination of the iris to the cornea, the compression of Schlemm's canal or any other part of the eye, are consequences, and not primary causes of glaucoma. I was somewhat surprised that, in a paper addressed to general practitioners, the author attached so little importance to the clinical symptoms in glaucoma, of a general character, such as gastric and febrile disturbances in connection with hemicranic headache. These symptoms often cause the practitioner to fail to discover glaucoma. I can recall a number of such instances. Last October a lady came under my care who had been under the treatment of a physician for four or five weeks for malarial fever and dyspepsia, which was the beginning of an undoubtedly characteristic and typical attack of glaucoma. But the attending physician's attention was attracted by the coated tongue, the nausea, vomiting, severe headache, and excited pulse, and he treated the patient for these daily attacks of headache which he diagnosticated malaria, and used antiperiodic remedies, utterly disregarding the condition of the eye, although the sight was at first nearly extinguished, and only returned to a certain extent after the attack lost somewhat its severity. Another case: A poor woman lost one eye from glaucoma ten years before; the eye was blind and hard, showing the characteristic state of an eye in which glaucoma had run its course. She was attacked by a severe pain in the head extending over the left side, could not sleep for several weeks, was nauseated, vomited, and showed symptoms of some general disturbance. The physician treated her for the stomach trouble and headache, and although she told him time and again that her sight was getting poor, and suggested that an oculist had better examine her eye, he paid no attention to this, and the result was that two months after this attack the sight was entirely gone and could not be restored. In still another case both eyes were neglected until the patient could perceive only a little flicker of light, before it was considered necessary by the attending physicians to pay any attention to the eyes. Dyspepsia, gastric fever, malaria, and sick headache were the diagnoses, and the treatment was in accordance. I think it is well to bring out these points, and to call the attention of every physician to the fact that such attacks sometimes mean something more serious than a disturbance of the stomach, and that when the patient during such attacks speaks of the eyes as being troublesome, or the sight as becoming dim, it is worth while to pay attention to it, and to remember that acute glaucoma is often ushered in with these general constitutional symptoms."

Dr. Lyman Ware said: "I have only a word to say about the disturbance of the equilibrium of secretion and excretion. It has been fully demonstrated that it is only by restoring the equilibrium that sight is saved. I quite agree with Dr. Hotz regarding febrile symptoms, but it is my experience that they are *secondary* rather than *primary*."

Dr. Henry Gradle said: "The cases which Dr. Bettman presented are of great interest from the fact that they have only lately been recognized. Dr. Gruening, of New York, was the first to point out that there existed affections apparently of the eye, but which in reality originated from the nose. I have watched for these cases ever since Gruening's paper first appeared, and would say that the cases in which the nasal trouble is *entirely* the cause of eye disease are not very frequent. But I have seen instances where affections of the eye were certainly complicated by nasal trouble, and the nasal trouble prolonged the eye disease. I recollect a number of cases of eye disease either kept up or originated by nasal trouble. The first of these is a pseudo-erysipelas of the lids, which is not an infectious disease, but merely a secondary affection of the blood-vessels, only resembling erysipelas clinically. It is entirely due to irritation and engorgement of the blood-vessels in the front part of the inferior turbinated bone. A second type of nasal affection giving rise to eye trouble is true periodical hay-fever and a non-periodical irritability of the nose resembling hay fever. I have published four cases, and have since seen another, of periodic conjunctivitis characterized by the formation of granules and follicles, which trouble always receded in winter, to re-appear again in the spring or

summer. In two of these cases a diagnosis of hay fever has since been made. I have seen a case which had been treated for trachoma by a number of specialists, where the history of the nose showed that the affection was of nasal origin. The same trouble may exist in a non-periodic form, and present all the symptoms of hay fever, the trouble not being limited to any season, but occurring in any part of the year, lasting a few days or weeks. But these cases are not common. In one of these cases I was able to effect a complete cure by cauterization of the nose. A third type of nasal affection giving rise to ocular symptoms is true catarrh of the upper and front part of the mucous membrane of the nose, where the membrane is distinctly reddened, and where there are generally slight and by no means prominent symptoms of catarrh. In these cases I have very frequently found troublesome epiphora without any stricture of the duct; in some cases the test was made by using delicate probes. Such cases, I can testify from my own experience, are entirely curable by simple treatment of the nose. I have found a not sharply defined case of asthenopia, due not entirely to the nose, but complicated with refractive trouble, where nasal treatment was necessary to complete a cure. Once or twice I have seen polypi play the same role, and a number of times I have found the starting-point of the irritation not in the front of the nose, but in the posterior part, in the form of the common adenoid vegetations.

This is a subject which has not been fully dealt with in literature, but I have several cases where the extirpation of the large post-nasal tonsil has given decided relief to the eye. Then I have found that in a few cases ulcers or chronic inflammation of the cornea were kept up by nasal trouble, which was probably started in the first place by a copious flow of tears from the eye. I have observed that local treatment by means of calomel, atropia, and the customary applications to the eye, proved inefficient, while the addition of nasal treatment hastened the cure of some of these tedious cases. The nose was probably normal to start with, but the continued flow of tears produced either small erosions or some little catarrhal troubles of the mucous membrane at the front of the nose, subsequently increased to chronic catarrh, leading to congestive obstruction of the tear passages, or exerting an unfavorable nervous influence upon the eye trouble. Finally, as a rare instance, I will mention one case which is now cured. The patient was sent to me for polypi, which, however, proved to be the minor trouble in the nose, the real trouble being an immense vascular tumor occupying the entire floor of the right side of the nose, covering the inferior turbinated bone and reaching about to the middle turbinated bone. The patient had been reduced in strength, and the slightest exertion on his part produced hemorrhage, therefore the most careful operative procedure was necessary. I finally succeeded in removing the entire tumor by the galvano-cautery in twenty sittings. As the tumor began to shrink the hemorrhage was less, but he lost thirty or forty ounces of blood in six weeks. During the latter part of the treatment his right eye began to bulge, and he complained of double sight. It has remained healthy, but there was an unmistakable development of vascular tissue in the orbit and behind the eye, which receded by the time the tumor had been extirpated from the nose."

Dr. Boerne Bettman said: "I was very glad to hear Dr. Gradle corroborate my statements. I am well aware that these cases are comparatively rare; although I have recorded in my case-book about twenty seen during the last two years. I am acquainted with the article published by Gruening. My attention was first called to the subject by the work of Hack, and since reading that I have made it a point never to allow an eye patient to leave my office until his nose has received a very thorough examination. I have seen a number of cases such as mentioned by Dr. Gradle, but I thought it better to describe to-night only the typical ones. The connection between ocular and nasal troubles is a point all oculists should bear in mind, and when they find no local cause for epiphora they should examine the nose."

Dr. A. P. Gilmore said: "I would like to add one word in regard to glaucoma, and that is, the importance of tension does not seem to me to have been sufficiently dwelt upon. Any careful general practitioner can ascertain whether the tension is increased or not, simply by comparison with the tension of his own eye. All pain referred to the eyeball, with or without the accompanying neurotic symptoms mentioned in the paper, does not mean glaucoma. Unless there is increased tension you cannot diagnosticate glaucoma. The author does not mention Badal's operation in the treatment of glaucoma. It is certainly entitled to a place among the operative measures. I will only speak of one point in Dr. Starkey's paper,

viz., epiphora. I do not believe, with many, that epiphora is due primarily to a stricture which prevents the escape through the nose of the natural amount of fluid secreted, but is due rather to reflex irritation causing an hyper-secretion of tears. In health the eye is moistened with a moderate secretion. When the lachrymal gland is removed the eye continues to be moist and the cornea retains its lustre. Tears are not essential to the lubrication of the eyeball; their function is to protect the eye against foreign bodies. A bit of dust under the lids will cause profuse lachrymation and the tears will flow over the face, not because of an obstruction to the natural amount of fluid secreted through the natural passage, but because of a hyper-secretion due to reflex irritation. For treatment I never use a probe larger than Bowman's No. 6, usually No. 4. I seldom find it necessary to make Bowman's operation in epiphora. I think its use is unnecessarily frequent. I use astringent and antiseptic solutions with a syringe small enough to be easily introduced into the puncture when slightly dilated. I am very careful to treat any nasal complications; it is impossible to treat diseases of the eye successfully without recognizing and treating reflex irritations of the nose."

Dr. Starkey said: "My paper was necessarily cut down very much. As first written I had given some space and attention to cases similar to those mentioned by Dr. Bettman. I had also spoken of the probability that in many cases of epiphora, where there had been inflammation of the tissues lining the lachrymal canals with partial closure, a continual irritation of the canal in some way, perhaps reflexly, so stimulates the lachrymal gland that the tears are poured forth more abundantly. There are well-known cases where the lachrymal canals have been completely closed by injury or operation, and yet lachrymation is not annoying, although the gland has not been extirpated; tending to show, as mentioned by Dr. Gilmore, that the normal secretion of tears is ordinarily very limited. It seems to me that in many instances lachrymation is due to irritation propagated reflexly, and therefore in treating such cases I thought of trying to restore the mucous membrane of the lachrymal canals to the normal condition, as well as to look for and treat points of irritation elsewhere."

Dr. J. E. Colburn said: "In cases of injury where there is danger of sympathetic irritation, a foreign body being lodged in the anterior chamber, iris, ciliary body, or the choroid, where the chances are that in order to give all the advantages of treatment the patient must necessarily be idle for a considerable length of time, and where the sight in the injured eye has been irretrievably lost, I think it advisable to make the operation of evisceration or abscission as early as possible.

The patient, if a laboring man, is then relieved from a long enforced idleness and anxiety, and the danger that lack of care frequently causes in this class of cases. Where the appearance is first to be considered, and the patient can be constantly under observation, the operation can be postponed, but with the strict injunction the patient is to be under constant surveillance. In a large majority of cases where there is great damage done and the foreign body is out of sight, it is safe and advisable to make the operation, trusting to that to save the other eye. In a case that came under my observation recently a piece of steel entered the anterior chamber near the centre of the cornea, passed through the iris and lodged in the sclera. No operation was performed, and the fellow eye became sympathetically affected, and on account of its sympathetic disturbance had to be removed. The steel produced some local irritation, and the eye was caught and rolled strongly toward the nasal canthus, and the piece of steel was found projecting into the orbit from the sclera and was removed. The track of the steel through the sclera was surrounded by a large mass of fatty degeneration, which was also removed. Vision remained about one-half."

Dr. W. Franklin Coleman said: "I agree with Dr. Colburn as to the desirability of timely enucleation in the case of a laboring man, to save his time, but should ophthalmitis set in I should not, under any circumstances, enucleate the eye. I believe it is rare for German operators to risk removing an eye in a case of ophthalmitis, but in England they scarcely hesitate to remove an eye under any circumstances. I have never regretted recommending a patient to have an eye enucleated, but I have sometimes regretted that I did not urge the patient to have the eye out in order to avoid the fearful risk of sympathetic inflammation. I am astounded at the position of so eminent an authority as Noyes, who says, 'I hesitate to enucleate the eye on account of appearances, and do not do so unless symptoms of irritation or inflammation appear which I cannot relieve with medical treatment.' In nineteen out of twenty cases the lost eye is not worth saving, but is a blemish, and an arti-

ficial eye would be more ornamental. And if a man wishes to get work he will deceive the very elect as to which is the real and which the artificial eye. I cannot see any advantage in not advising enucleation where the eye has been injured to such an extent as to menace the fellow eye."

Dr. Gilmore asked Dr. Holmes why he did not try a magnet?

Dr. Holmes replied that he had been in so much doubt what to do that he thought best to first try incision and forceps. He did not believe the best magnet could have liberated the end of the steel, buried in the tissues of Fontana's space. It is remarkable that so long a piece of metal could have been thrown through the cornea, making so minute an opening, and lodged in the anterior chamber, as described, without injury to the iris or lens.

Dr. Coleman said: "To my mind the magnet in the eye is a delusion and a snare. For instance, if you introduce a magnet within the eye, not knowing where the foreign body is before placing the point of your magnet, you have to search the whole cavity of the eyeball and reduce it to a jelly before you can extract the body. Granted no great harm is done if you do not extract it with the magnet, for you can afterwards enucleate the eye. But so far as I have tried it, and have seen others experiment with the magnet, it does not give satisfaction."

Dr. Holmes replied: "That is very true in many cases where the steel cannot be seen with the ophthalmoscope; but I think where a view of the foreign body can be obtained early, the magnet may be employed with brilliant results. There are now so many cases reported with excellent results after extraction with the magnet, that I cannot think it a delusion and a snare by any means."

Dr. Colburn said: "I recently saw an interesting case in which the foreign body was lodged about half way between the ciliary body and the entrance to the optic nerve. The operator cut through the sclera about where he thought it was lodged, passed the magnet in and brought out the foreign body apparently without wounding the retina at the point of attachment. The patient made a good recovery."

NEW YORK ACADEMY OF MEDICINE.

Regular meeting, February 3, 1887.

A. Jacobi, M. D., President, in the chair.

The President read an address in which he acknowledged the obligations imposed upon him in accepting the honor of the presidency. He pointed out the good work being done, and referred to the steps necessary in order to make the Academy even more successful and useful than it had hitherto been.

Action was taken preparatory to purchasing a site for the proposed new building.

On Detecting and Locating Metallic Masses in the Human Body by the Indication-Balance and the Telephonic Probe.

Dr. John H. Girdner described these two instruments, the induction balance and the telephonic probe, which had been invented by Professor Bell for the purpose of detecting and locating metallic masses in the human body, such as bullets. An apparatus was prepared by Prof. Bell for the purpose of detecting the bullet in President Garfield's case, but it failed, owing to haste of construction and the fact that the patient, as was learned afterward, was lying on a steel mattress. The instrument had been so far perfected, that at present one was able with it to locate a bullet distant six inches from the surface. In the circuit of the induced current is a telephone receiver, which conveys a musical sound whenever the coil of wire called the explorer is passed over the body in the locality of the metal. The sound grows louder and louder until the explorer rests directly over the metal. Having detected the piece of metal in this manner, the telephonic probe comes into use in placing its exact locality. In a circuit is a telephonic receiver; one pole is connected with a metallic plate laid upon the body, and the other, terminating in a long slender probe, is passed through the anæsthetized skin down upon the bullet, which, when touched, causes a clicking sound in the receiver. The practical working of the apparatus was demonstrated upon a wounded soldier, and also upon a piece of beef into which a piece of lead had been placed.

The Use of Traction in the Treatment of Club-foot, with a Consideration of Some of the Mechanical Principles Involved, and a Description of an Antero-posterior and Lateral Traction Apparatus.

Dr. Newton M. Shaffer read a paper with this title, exhibiting numerous diagrams and apparatus, and explaining the principles involved in the motion of the foot upon the ankle, and the violation of these principles in the use of apparatus usually employed. His own apparatus was intended to re-estab-

lish the natural form of the foot by making traction in the directions observed in the motion of the healthy foot, namely, by drawing the heel downward and forward and the toes upward and forward when talipes equinus existed, and in varo-equinus employing at the same time lateral traction. The shoe should be made to fit properly, and in that case it was simple and effective in use, and usually did away with the necessity for tenotomy.

Editorial Department.

Periscope.

A Case of Free Drainage of a Phthisical Cavity.

The following remarkable case is reported by Mr. Arthur Neve, F. R. C. S., in the *Lancet*, and is highly suggestive:

A young man, haggard and wasted to a degree, was admitted into the C. M. S. Mission Hospital on April 10, 1886. For a year he had been suffering from violent cough and profuse expectoration. His appearance was that of a man in the last stage of phthisis. His fingers were much clubbed. The expectoration amounted to a pint and a half or two pints in the twenty-four hours. It was tough, and in large flocculent, purulent masses. Microscopic examination showed a very considerable proportion of pus-cells, with elastic fibres, etc., and swarming with bacilli. Examination of the chest revealed the presence of cavities in the upper and anterior part of the right lung, while the right base and most part of the left lung was fairly healthy. The left apex appeared condensed, with possibly commencing softening. For nearly three weeks the patient was treated with cod-liver oil, tonics, eucalyptus, and creasote spray, and counter-irritation. During this time there was no improvement, and the patient (a troublesome one) was clamorous for something to be done. Accordingly on April 29th, having administered chloroform, I made an incision two inches long close to the right nipple, through which a corresponding portion of the fourth rib was resected, with the periosteum attached. The pleural surface was, as I expected, firmly adherent. I then forced my finger inwards and upwards in the direction of the cavities. There was no such large cavity close to the wound as I had hoped to find; but upwards it entered two small cavities. The tissues were hard, but friable. I did not attempt to open the cavities on the axillary side, deeming that they would drain by the bronchi into the wound. A large-sized drainage-tube, six inches long, was passed into the lung, and the wound closed by a pad of gauze and a saw-dust bag. Hemorrhage was quite inconsiderable, and the air whistling through the wound gave promise of good drainage. Within two days the expectoration by the mouth was diminished to three or four ounces, and was no longer accompanied by the distressing cough which the man had complained of. There was, however, much pain about the wound. It was daily washed out with corrosive sublimate solution, and pure oil of eucalyptus was poured into the tube. At first this gave rise to cough, but toleration was established. Inhalations of creasote and eucalyptus were continuously maintained by keeping the pad on the wound moist with them. The discharge from the tube was chiefly muco-purulent; at first bloody, later thick and tenacious, but progressively less so. About the fourth week the patient began again to complain of the drainage-tube (which he had himself removed several times during the first two days); a little blood also appeared on the dressings; so, fearing ulceration into the vessels of the lung, I removed it altogether. In the early part of June the sputum continued healthier, and he went home. On the 24th he returned. The improvement was then striking, especially in the local signs. The chest round and above the wound was considerably contracted, and sucked in. The sinus was freely open, and upon coughing some mucus was expelled from it. The healthy area of the lung seemed increased. The apex of the left lung, however, showed more signs of breaking down. He remained under observation in hospital for two days, and was photographed. The expectoration was about ten ounces in twenty-four hours, but was chiefly clear and watery, with a few nummular masses similar to those of which it formerly entirely consisted. His cough troubled him only in the morning; he slept and ate well, almost ravenously, and gained strength, though but little flesh. He was then sent to a mountain sanatorium 8500

feet above the sea. Up to this point the improvement effected was entirely by means of the operation. Since that time I have not seen the patient, but occasionally receive reports from his friends. After September he became weaker. He is said to wander over the country, is seldom at home, and does not work. There still remained a small opening in the chest.

Salol as an Antiseptic.

M. Quinquaud recently presented the following communication from M. Pinet to the Société de Biologie. The salicylate of phenol, or salol, was discovered by M. V. Nercki. It appears as a white powder, insoluble in water, but soluble in alcohol. It has an aromatic odor, and, according to the author, has no taste. Experiments have been made with salol by M. Nercki, who attributes to it the same antiseptic properties as those of salicylic acid, whether it be employed in the form of powder or in an oily solution. Ten cubic centimètres of septic fluid produced by the putrefactive fermentation of the muscles of a frog steeped in water, were put into a test-tube, and set aside for comparison. This liquid, which was very turbid, exhaled the special odor of putrefaction, and contained a considerable quantity of all the bacteria ordinarily met with in putrefactive fermentation. Ten cubic centimètres of the same fluid were put into tubes containing respectively five, ten, fifteen, and twenty centigrammes of salol in powder. A second series of tubes was prepared, each containing a like amount of the same septic liquid, but with corresponding weights of salicylic acid in powder instead of salol. The tubes were allowed to stand for a few hours, when it was found that the liquid in tube No. 2, which contained fifty centigrammes of salicylic acid to one hundred grammes of the mixture, although still a little turbid, was notably clearer than the liquid in the first tube, which was set aside for comparison. The microscope revealed but very few bacteria, with little movement. The others were inert at the bottom of the preparation, the micrococci having lost their Brownian movement and their refraction. The putrid odor had almost entirely disappeared. The liquid in tubes Nos. 2, 3, 4, and 5 presented the same characteristics. At the end of twenty-four hours the liquid in tube No. 2, which contained salicylic acid in the proportion of one-half per cent., was found to be absolutely clear, and entirely free from putrid smell. The same was found to be the case as regards Nos. 3, 4, and 5. The liquid in the tubes containing the salol was found at the end of six days to be quite as turbid as the primitive liquid. The odor of putrefaction, although somewhat masked by the odor of the salol, was nevertheless distinct. On the third day, there appeared on the surface of the liquid a grey pellicle, which, when examined with the microscope, was found to contain a large quantity of micrococci, and an infinity of bacteria and monads. Following up these experiments, it was found that salol in powder, in doses of 10 per cent., in no way hindered the development of putrid fermentation. From this it will be seen that salol and salicylic acid are far from being equally antiseptic, since five centigrammes of salicylic acid in ten cubic centimètres of putrid liquid arrested fermentation, while one gramme of salol in ten cubic centimètres of the same putrid liquid, had no such effect. The oily solution of salol employed under the same conditions produced like results. Finally, if in those tubes in which the salol had remained without effect, and in which the liquid was turbid and had a putrid odor, five centigrammes of salicylic acid were placed, the liquid was found, after twenty-four hours, to be clear, and to have lost all smell. As regards the anti-microbic action of salicylic acid, the following observation is mentioned: In a case of dental caries causing excessive pain, the author, by the advice of Professor Vulpian, applied to the affected part a paste, formed of salicylic acid and water. A first application of this paste brought about a notable diminution of pain; a second, two hours later, caused entire cessation of the pain within a few minutes. This observation is interesting, as it appears to indicate that the pain was in some way connected with the presence of microbes in the dental cavity.

Acute Disease in Opium Habitues.

In treating acute disease in persons accustomed to the consumption of opium, it is highly important to continue the customary narcotic. This is illustrated by a case quoted by Dr. Richardière, of Paris. The patient, a physician in one of the suburbs of Paris, had contracted the habit whilst suffering from a painful affection of the stomach, and it had now become inveterate. In consequence of fatigue and exposure in attending his patients during several nights in succession, he caught a slight cold, with sore throat. A few days later, after further exposure, he had fever and headache, together

with pain in the right side. During the day he grew worse, and had several fits of coughing. The following night he had rigors, and complained of oppression. Tubular breathing was heard in the lower half of the chest on the right side, and there was marked dullness on percussion in the same region. The fever was intense; the respiration was labored, superficial, and very frequent. The expectoration was yellow, and much thinner than in typical pneumonia. The weakness and irregularity of the heart's action, and the excessive rapidity of the pulse, made the prognosis very grave. The oppression became intense; the respirations numbered from 60 to 70 in the minute. The patient had frequent attacks of suffocation of a degree of severity exceeding anything M. Richardière had ever seen in pneumonia, and bearing a striking resemblance to those of asthma. In his efforts to breathe, the veins in the patient's neck became swollen, and his face violet in color. At last, after a series of fruitless attempts, he succeeded in expanding his chest, and respiration began again, but was extremely frequent and hesitating. There appeared to be only one explanation of these attacks. M. Richardière knew that the patient was in the habit of taking morphine, having already treated him for large abscesses in the legs which were caused by the injections, and he thought, therefore, that the sudden privation of the habitual stimulant might count for something in the production of these attacks of coughing, which were very different from those which occur in the broncho-pneumonia of adults. The patient was young, vigorous, and of sanguine temperament. The heart contracted badly, probably on account of the inability of the left ventricle to force the blood into the lungs, which had become in part impermeable. Bleeding seemed to be clearly indicated, and accordingly from 500 to 600 grammes of blood were withdrawn. An expectorant draught was given, together with an injection of morphine. The next day the symptoms were unchanged; but after another injection of morphine, the dyspnœa was somewhat diminished. Blood was again drawn to the amount of 400 or 500 grammes. During the evening the patient's state seemed to be worse; the respirations were 70 in the minute; the pulse was thready, and more rapid than on the previous evening. The face was of a violet color, and the extremities were cold. The patient seemed to be past hope, but as a last resource subcutaneous injections of ether were made every two hours, together with three fresh injections of morphine. On the following morning there was a notable improvement, and in spite of subsequent recrudescence the patient finally recovered. Although the attacks of dyspnœa in this case presented only an asthmatic form, M. Richardière thinks they should be attributed to chronic morphine poisoning; and he believes that a fatal attack was only prevented by recourse to the stimulant for which the system was craving.

Aspergillus Nigricans.

Before the Academy of Medicine in Ireland, Mr. Story exhibited and described microscopic specimens of aspergillus nigricans, which he had removed from the auditory meatus of three individuals suffering from deafness and inflammation of the external ear. He also showed a fourth fungus of an undetermined character, but most probably also one of the aspergillus tribe. Mr. Story stated his conviction that the fungi were the cause and not the consequence of the ear disease—a view which had been advocated by some writers on the subject.

The President said he had seen a few cases of aural fungi. In one of these there was intense pain in the left ear, and the meatus was partly blocked up with a white cottony material. A brother of the patient was at the same time being attended by Mr. Swanzy for otomycosis, contracted by lying on hay or damp vegetable matter in the summer time, and he (the President) asked Mr. Swanzy to see his case. It was impossible to resist the evidence that the fungus was the direct cause of the disease. The invasion by it of the deeper tissues had been conclusively proved. He would ask Mr. Story whether in any of his cases he had noticed any special cause which led to the production of the fungus, such as dealing with yeast or any contact with decomposing vegetable matter. The aspergillus, he believed, was not confined to the ear, but was also occasionally found in the bronchial membranes.

Dr. Mapother mentioned that in the year 1880 he himself had an acute attack of otomycosis. He had never suffered, either before or since, from any aural disease. One night he went to bed in a house in the suburbs of Dublin with his hearing perfect; and the following morning he arose almost completely deaf. He bore the affection for one day, and on the next consulted Mr. Swanzy, who, partly with forceps and partly with the syringe, removed a quantity of

white cottony material from his ears. The only sensations he had besides the deafness were stuffing and a sort of ramming, as if something like cotton-wool was being pushed into both ears. The material removed from his ear was examined by himself and his friend, the late Dr. Richardson, and they both came to the conclusion that it contained aspergillus. Which of the seven or eight different forms it was he could not say; but, as well as he remembered, it was like the first form described by Mr. Story. The shape of the growth resembled the aspergillus, or holy-water sprinkler, used in the Roman Catholic Church. After the extraction of the fungi from his ears, and a week's washing with sulphuric acid, they disappeared and never grew again. He had observed that the wall-paper of the room, next to which he had slept, was almost completely separated from the wall by damp; and believed that it was that which produced the fungi. Since the wall had become dry, no similar attack of mycosis had occurred to any one else occupying the room.

Mr. Story, in reply, said he remembered being consulted by a farmer who, after sitting up all night with a sick cow, had stuffing and pain in his ears next morning, which were found to be caused by aspergillus.

A Case Illustrating the Need of Caution in the Use of Salicylic Acid.

Dr. W. T. Freeman thus writes in the *Lancet:*

A short time ago I was attending an old lady of fifty-nine years of age. My attendance to the time of her death extended over a period of three weeks, but she had been attended for a few weeks previously elsewhere by another medical man. Her symptoms ran as follows: A great feeling of malaise, of depression of spirits, with always more or less of a slight headache; tongue coated with brownish fur, especially at the back; sallow skin; stools clay-colored; bowels opened freely every day; pulse during the whole of the three weeks full, and beating at the rate of from 105 to 110 per minute; never any rise of temperature; specific gravity of urine about 1020, acid, with distinct trace of phosphates, but no albumen or sugar. She was restless at times at night, even to the extent of getting out of bed aimlessly. I diagnosed the case as an obscure one, but expressed my opinion that she was suffering from congestion of the liver, and probably also from some congestion of the brain. The patient was generally of a feeble habit. On the twentieth day of my attendance, although she showed no alarming symptoms whatever, and she became but slowly better, I suggested a consultation. She had improved, however, in these respects—the motions had become of an almost natural color, and the headache was better; the rest of the symptoms were unchanged. The treatment to that day had been attending to the bowels, regulating diet, and keeping the patient quiet, whilst medicinally she had been taking a simple effervescing mixture of tartaric acid and bicarbonate of potash, with ten grains of bromide of potash in each dose, three or four times in the twenty-four hours. After most carefully considering the case, the gentleman I had called in came to the conclusion that a rheumatic taint was at the bottom of the remaining mischief, and prescribed for her fifteen grains of salicylic acid, together with small doses of carbonate of soda, carbonate of ammonia, and tincture of nux vomica three times daily. In this treatment I coincided. She was quite in a natural mood on the afternoon that we saw her together, and we were agreed that there was no cause for alarm, and that there was reasonable hope of her being restored to her usual state of health in the course of a few weeks. I saw her no more till next morning; she had then taken three doses of the salicylic acid mixture. I found her comatose and rapidly sinking. The urine contained albumen. We had another consultation as soon as possible, but she died in the course of a few hours. Although probably the brain symptoms were more severe all along than I expected, and most likely the head mischief would have ended her days, yet I cannot help feeling that our last attempts to cure our patient only resulted in the abrupt snapping of the thin cord of life she had left to her.

The Pathology of Colles' Fracture.

At a recent discussion at the Pathological Society of London, Dr. D'Arcy Power read a paper on the Pathology of Colles's Fracture, and drew attention to the large proportion of fractures of the lower end of the radius in which the lower fragment was comminuted into the joint. He believed that, from a pathological standpoint, this variety of fracture is more common than the simple form ordinarily described; and he held that, without dissection of the injured part, it was often impossible to distinguish the simple from the comminuted fractures, since the deformity might be identical. He

related the case of a man, aged thirty-nine, who fractured his wrist, and sustained such other injuries that he died. During life, and even after death, when a more careful examination could be made, the wrist presented the symptoms of an ordinary Colles' fracture, and it was only upon dissection that the true nature of the injury was apparent. The lower end of the radius was seen to have undergone a very complete crushing, the wrist-joint being implicated in more than one place. Since the occurrence of this fracture, Mr. Power had examined several other cases which appeared to be of the ordinary type, but which, upon dissection, proved to be in reality comminuted. He exhibited the six specimens before the Society. He had also collected details of cases in which, after almost identical injuries, a fairly useful joint had resulted. He concluded his paper by observing that, although the pathological interest attaching to these cases was great, he believed that the clinical importance was but small, since it was difficult to distinguish between the two classes in the first place, and when that was done the final result appeared to be almost equally good. In examining the specimens preserved in the various pathological museums in London, Mr. Power had only found twenty-five cases of simple fracture, as against thirty-two in which the lower fragment of the radius being comminuted, the fracture had extended into the joint, thus bearing out the observation of Mr. Clement Lucas, that pathological specimens showed a very large proportion of comminuted fractures.

Sir James Paget asked if the history of the manner in which the patients fell was known.

Mr. Gilbert Barling had seen cases of simple, impacted, and comminuted fracture into the joint, but this anatomical knowledge would not be of therapeutical value.

In reply, Mr. Power agreed with the last speaker, and said that indirect violence was the cause of all the fractures, but the exact method of its application was very difficult to discover.

Reciprocal Influence of Diabetes on Syphilis.

In a recent article published in the *Journal des Connaissances Médicales*, the question of the reciprocal influence of diabetes upon syphilis, and of syphilis upon diabetes, was discussed. The question of the connection between diabetes and syphilis is of recent date. Different authors have only kept in view the fact of syphilis being regarded as the cause of diabetes, and have paid but little attention to diabetes co-existing with syphilis. It is the latter point which gives great interest to the recent thesis of M. Arnaud. Two circumstances may arise where diabetes and syphilis are co existent:

1. The patient may have been suffering from diabetes for a longer or shorter period when he contracts syphilis, and the latter complaint is modified in its evolution and progress from the fact of diabetes having preceded it.

2. Diabetes developing after syphilis seems to be the direct or indirect consequence of that disease.

The results of M. Arnaud's observations on this subject have led him to the following conclusions: When diabetes has pre-existed, it modifies the clinical aspect of syphilis, either because it induces cachexia, and thus renders the patient less able to resist the invasion of the disease, or because it exercises an injurious influence upon the anatomical elements by bringing them into direct contact with the sugar contained in the pathological secretions of the human economy. It cannot be denied that syphilis may give rise to diabetes, which may be more or less persistent, owing to the changes in the blood and tissues which it constantly produces. Syphilis may bring on another form of diabetes through tertiary products (gummata) becoming developed in the surrounding parts of the fourth ventricle, and compressing the centre of glycosuria described by Claude Bernard. When syphilis develops in a diabetic patient, infective chancre and secondary lesions have a tendency to ulcerate. As these deviate from their ordinary aspect, they may give rise to an error in diagnosis. Under these circumstances, the evolution of syphilis appears more rapid than in a normal case of the complaint. According to some writers, sugar disappears when specific symptoms show themselves. M. Arnaud's observations prove that sugar seems to leave the urine more rapidly in these cases than in ordinary diabetes. Syphilis will prove more serious in diabetic patients than in others. Anti-diabetic should be combined with anti-syphilitic treatment in such cases.

Antipyrin in Phthisis.

Antipyrin has been shown to have various uses, but if the success which has been reported by Dr. Zakrzhevski in a paper contributed to the *Russian Military Medical Journal* attends the practice of other medi-

cal men, this drug will hereafter be looked upon as almost a specific. While under ordinary methods of treatment the mortality of phthisical patients in the Helsingfors Hospital was 50 per cent. during the eight months in which the antipyrin treatment has been carried out, not a single case has proved fatal, many of the patients having, on the contrary, improved so decidedly as to be able to return to their homes. The author much prefers the hypodermic method of administering antipyrin, as the effect is produced in less than an hour, whereas when the drug is given by the mouth no effect is produced for from one to three hours. The action of antipyrin is to increase the force of the cardiac contractions, and so to raise the blood-pressure. In phthisical patients it slows the pulse, but never quite to the normal rate. It also slows and deepens the respirations, and the digestive functions are improved. No albuminuria or other sign of renal disturbance was observed. With regard to the dose Dr. Zakrzhevski finds that it should be regulated by the strength of the patients. In a man with phthisis, who was still fairly robust, a full dose of ninety grains was required in order to produce the best effect; whereas in greatly debilitated typhus patients ten or fifteen grains were quite sufficient, and in cases where there was decided exhaustion it was found that a dose of sixteen or seventeen grains was the largest that it was advisable to give.

On Primary Nerve Suture.

At a meeting of the Medico-Chirurgical Society of Leeds, England, Mr. Rowe described a case where the ulnar nerve and artery were both divided. After securing the artery, he joined the cut end of the nerve (the proximal being much retracted) with a carbolized catgut suture passed through the nerve. Two days after the operation the numbness was less. In five days and a half the sensation was the same, but there was some slight movement in the muscle. In thirty days sensation was slightly impaired, and motion was definite, but not perfect. Shortly afterwards the man pursued his occupation. Mr. Rowe referred to cases by Favel, Nélaton, and others; in some sensation partly returned at the end of the second day, recovery taking place at the end of a week. In a case of primary nerve suture reported by Laugier, recovery began the day of operation. In Page's cases it occurred in nine days; in Pye's cases, in eight days; but there were some errors of localization in the former. Mr. Rowe compared the rapid restitution of function in primary suture with the later development noticed in cases of secondary suture, referring specially to a case where the sciatic nerve was sutured by Mr. Wheelhouse, perfect function being only restored after several months.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. Augustus V. Park has published two addresses read before the Chicago Medical Society, the one describing a case of antepartum hemorrhage at term, the other a case of pyelitis of nineteen years' duration, caused by a renal calculus. Both recovered.

BOOK NOTICES.

The Year Book of Treatment for 1886. Cloth, 8vo., pp. 304. Philadelphia. Lea Bros. & Co., 1887.

This Year-Book is an English work compiled by a number of London physicians, giving with great brevity the therapeutic advances in their respective specialties during the year ending with September, 1886. It is carefully collated, and well indexed, both with regard to authors and subjects. As a handy means of "keeping posted" it is to be recommended; and the fullness of references with which it is provided will enable a reader to look up a subject further in which he becomes particularly interested.

Picrate of Ammonia in Malaria.

An East Indian surgeon, Dr. H. M. Clark, in a recent issue of the *Lancet*, extols this drug. His experience has led him to the conclusion that in all varieties of intermittent fever, and in malarial neuralgias, picrate of ammonia is a valuable antiperiodic, and it is an efficient and perfect substitute for quinia. It has the following advantages over quinine: 1. It is much less expensive. This is an important consideration where hundreds of cases of malarial diseases have to be treated annually. 2. The dose given is very much smaller. 3. It does not produce the unpleasant effects that quinine does —headache, deafness, tinnitus, etc.; nor does it disorder the digestion or cause nausea, as quinine is apt to do, in the doses in which it has sometimes to be given.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

PASTEUR AND HIS EXPERIMENTS ON HYDROPHOBIA.

What a pity that the brilliant promises of M. Pasteur to protect the human race from the terrors of hydrophobia have aborted so completely! The sad results of case after case have been traced out, and we are driven to the conclusion that his method of inoculation has simply shown that no such means, so employed, is able to counteract the canine virus.

Pasteur proceeded on the "germ theory," on the conviction that the hydrophobic poison was some form of living, self-propagating organism, whose power of self-multiplication could be destroyed by exhausting the soil, as it were, by an allied organism of innocuous character. Such is broadly the theory of all theories of inoculation, and it derives a certain plausibility from the well known phenomena of many so-called zymotic diseases. Just now this theory is fashionable, although there are signs that it is approaching its period of wane.

Certain it is that Pasteur has disappointed the expectations of the public and the profession—expectations indiscreetly raised and stimulated by the public press, and by the premature confidence of Pasteur himself. How much better had it been if he had quietly pursued his experiments in his private laboratory and the hospitals, without this untimely announcement of them.

But Pasteur has always been an *idéologue.* His earliest chemico-physical discourse relating to the symmetry and asymmetry of crystalline bodies was an idea and not an observation, and the extreme vogue which it enjoyed at one time has now disappeared. It has not been productive of such wide results as he anticipated and announced. It remains as a scientific cnriosity, not as a pregnant truth of nature.

The undue haste of this gifted man to proclaim theories which cannot be verified should be a lesson to all workers in the field of science.

THE VALUE OF THE DIGESTIVE FERMENTS.

A subversive article appears in the *Transactions* of the Irish Royal Academy of Medicine from the pen of Dr. J. M. Purser. It is upon the therapeutic uses of the digestive ferments—pepsin obtained from the stomach, and trypsin from the pancreas.

He attacks without gloves the value of both of them as administered by the mouth in the usual way. Of the pancreatic ferment, he says: "It is evident that it is useless to administer trypsin as a drug, for its

activity will be destroyed if it is administered while the stomach is digesting and contains acid, while if it be given fasting when the stomach is empty and does not contain acid, it is incredible that it could pass through the stomach and lie in wait in the duodenum until the next meal be taken, and, having undergone stomach digestion, has passed through the pylorus."

As to pepsin, in any of its varied preparations, he is almost equally positive. He points out that pepsin is almost always found in notable quantities in the contents of the stomach, and believes this shows that it is not its absence which leads to dyspepsia, and winds up his discussion of it with the words: "I think that pepsin, like the other ferments, should be banished from the list of drugs employed for administration as internal medicine."

To these theoretical objections may be opposed clinical experience, which has repeatedly shown these drugs to be beneficial. But to this Dr. Purser replies that in a similar manner thousands of patients have been cured by homœopathic granules, by breathing through a solenoid, or by being put to bed with a horse-shoe magnet. He believes all the digestive ferments to have no higher and no other value as internal medicines.

He considers their only proper use to be to digest food in clean vessels outside the body and to administer the digested material. His position, though a bold and subversive one, must arrest the attention of scientific therapeutists.

THE ENGLISH CONTAGIOUS DISEASES ACTS.

These acts have now been in operation over twenty years, with excellent and steadily improving results. Regiments stationed in cities where the Acts are not in operation have about forty per cent. more or less disabled every year with some form of contagious venereal disease, while where the Acts are enforced this number is reduced to 15 or 18 per cent.

The practical working of the Acts may be briefly described, as they continue to be grossly misrepresented by their opponents. The territory is divided into stations, in each of which is a venereal hospital, with medical officers and female nurses in attendance. Each district has a superintendent to whom is reported by the police any woman who appears in public offering herself as a prostitute. The police are instructed to be very careful and guarded in their reports, and to act only on as clear evidence as is possible in cases of this kind.

The woman, when reported, is brought before the superintendent, who urges her to leave this mode of life, and warns her that if she continues she must pledge herself to appear for a medical examination every two weeks. Usually the women consent at once, and are often glad of the chance to be thus protected against the unfortunate results of their occupation. If diseased, they are sent to the hospital and properly treated. If incurable, she may remain for nine months, and is then discharged, but not permitted to reappear in her former vocation.

In spite of the most active opposition of ladies, clergymen, sentimentalists, and other wholly ignorant and prejudiced parties, and in spite of the howl that these Acts gave a quasi-legal recognition to prostitution, they have been continued with great advantage to the English army and navy, and with yet greater to the wretched women whom they most nearly concern.

REPORT YOUR RARE CASES.

Physicians sometimes ask, Why publish the records of cases which are so rare that the practitioner meets them no oftener than once a year or so?

The answer is, precisely because they are rare. A commonplace case of a common disease gives no anxiety to the attending medical man, and therefore incites him to no study of its features. He is not at a loss to deal with it, and asks no assistance.

But when he meets symptoms and complications which are unusual, he will, if an honest and intellectually active man, seek to find some parallel instance in the volumes of his library or in recent periodicals. It is precisely in such cases that he desires guidance and asks for the experience of others. These are the spurs to his intelligence, and the tests of his devotion to the science he cultivates.

What he asks of others he should give in return. When he comes across a rare case, a malady presenting unusual features and remarkable complications, he should set about unraveling them to his own satisfaction, and not stop there, but he should write out a history of the case and send it in to be recorded in the medical press. Thus he will not only benefit himself but others, and will have the satisfaction of feeling that he has in some measure paid that debt which Lord Bacon says every man owes to his profession.

We take this opportunity to say that our columns are always open to the reports of

such cases, and we urge our readers to send them in for publication. They belong to that best and highest grade of scientific literature, the records of the original observations of intelligent observers. We hope that this invitation will be accepted by many, and that a series of such cases will be sent us.

Notes and Comments.

When to Operate in Uterine Cancer.

In a discussion of this subject lately, Dr. J. Williams, of London, states that all cases of cancer should be operated upon, provided they are met with at a period sufficiently early to justify the hope of effecting a radical cure. But what are the physical signs which justify this hope? The pathological condition which justifies it—be the cancer in the portio vaginalis, the cervix, or the body—is that the disease has not passed beyond the uterine tissues. This, however, is not easily discovered either before or during the operation. Frequently, indeed, the after results prove that it was too late, even in cases which appeared to be favorable. The physical signs generally relied upon are mobility of the uterus, absence of induration around it, and absence of affection of the glands. In endeavoring to establish these points, the examination should be made under an anæsthetic, and the whole pelvis should be explored by the vagina and by the rectum. In spite of every care, however, clinical investigation may mislead, because the disease may have passed beyond the limits of the uterus and yet give rise to none of the physical signs mentioned. The pathological condition present is most easily established by clinical examination in cancer of the portio, for when the disease has reached the vaginal vault it gives rise to superficial induration at the place invaded, and this is more easily discovered than when induration of a slight degree is present in deeper tissues. In such cases, and indeed in all cases, the rule should be to make the incision in the vaginal wall wide of the indurated part. In this means alone lies any hope of preventing recurrence.

Therapeutic Value of Ergotine.

A European physician, Dr. Savitski, observes that ergotine has been used with success in the treatment of many affections—e. g., by Vidal in prolapsus recti, by Hunt and Pepper in diabetes, by Saunders, Murrell, and Noakes in diabetes insipidus, by Allan for the cough in some lung affections, by Granzio in obstinate constipation, by Gauldmel in the night-sweats of phthisis, by De Martini in spermatorrhœa, by Demange in some forms of typhoid fever, and by Girma in general paralysis. It has also been employed in chorea and dysentery. The theory of its action in these diseases he does not pretend to expound, but he calls attention to the similarity of the action of quinine and ergotine. Both, he says, undoubtedly cause contraction of the uterus and the spleen, the effect of quinine on the uterus having been scientifically worked out in a dissertation published by T. T. Smolski in 1876, and that of ergotine on the spleen having been shown by Dobodchiki (*Vrach*, 1880), and by Semchenko (*Vrach*, 1883). This similarity led him to think that one of these drugs might serve as a substitute for the other, and he therefore made a large number of observations on the effect of ergotine upon the cases of intermittent fever occurring in the Lubinski regiment with excellent results, especially where an enlarged and tender spleen was present. He finds that a combination of ergotine with quinine acts very satisfactorily, and that in this way considerable quantities of quinine can be saved, as half the dose of quinine which would be required if given alone will suffice if combined with ergotine. The preparation of ergotine used was Bonjean's, the dose in chronic cases being about a grain three times a day.

The Causes of the Uterine Souffle.

This question has been discussed by a German writer, Dr. Wehmer. He had a case in which the seat of origin of the ordinary uterine souffle could be clearly and experimentally demonstrated. A. Z., multipara, pregnant nine months; abdomen very pendulous. The recti muscles were so widely separated as to leave below the umbilicus an interval of twenty centimetres (eight inches) between one another. In this interval the abdominal walls were extremely thin and translucent, so much so that through them a large pulsating blood-vessel could be seen on the left side running in the uterine wall, and followed for a distance of ten centimetres (four inches). On auscultating this vessel, a distinct whizzing bruit was audible, synchronous, with the maternal pulse, and the movement of the arterial wall could be readily felt with the finger. Pressure with the stethoscope or the finger completely silenced the bruit. Anæsthesia also

brought it to a standstill, owing probably to the co-existing fall of intra-abdominal pressure; the bruit returned when the woman regained consciousness. During the labor-pains the note of the souffle reached a higher pitch, and became musical. After delivery it continued audible for two days, with diminishing distinctness. Wehmer believes this to be the first case in which the seat of origin and the various circumstances affecting the souffle have been so capable of demonstration, and here they were so owing to the existence of an unusually large branch of the uterine artery.

Medical Uses of Spartein Sulphate.

A Russian writer, Dr. Gluzinski, gives the results of some observations, both physiological and clinical, on the action of sulphate of spartein. Its main action is to slow the heart; besides this, it raises the blood-pressure. On cold-blooded animals it acts with a greater degree of intensity than on mammalia. The action on mammalia may be divided into three periods or stages, during the first and last of which the effects are more marked than during the second. Indeed, in some cases the heart is even quickened during the second period. This may be explained by the existence of some abnormality or pathological change in the irritability of the vagus or of the heart muscle. The reflexes are at first increased, afterwards diminished. Death occurs from asphyxia, and is due not only to the effect on the medulla, but to that experienced by the respiratory muscles. The therapeutic use of spartein is limited to the first stage of its action. Its value consists in the rapidity with which it acts. In some cases, within an hour after the first dose the pulse begins to improve, as well as the subjective sensations of the patient, and no irregularity is produced. Spartein has not so powerful an action as digitalis. It may, however, be useful in cases where the condition of the patient renders it unadvisable to wait for the more tardy effect of digitalis, and it may therefore be used as an adjunct to the latter drug, besides which it may be prescribed where circumstances exist which contraindicate the use of digitalis.

Indications for the Use of Nitro-glycerine.

Dr. Trussewitsch, in an instructive paper on the use of nitro-glycerine, published in the *St. Petersburger Medicinische Wochenschrift*, points out that the value of this drug in various affections—angina pectoris, migraine, and neuralgia (which he describes as angioneuroses), as also in sea-sickness, some forms of anæmia, faintness, palpitation, and other diseases—depends upon the existence of an irregular distribution of blood, which condition may be inferred from a certain degree of pallor of the skin, especially of the face, often co-existent nith a weak pulse and a small rigid radial artery, which frequently is situated at some depth. When, on the other hand, headache and neuralgia occur in patients with chronic congestion of the subcutaneous veins of the face, nitro-glycerine is to be avoided; and similarly it is of no use in asthma, when the face is reddened in consequence of emphysema. If, however, a pale face exists with angina pectoris, migraine, giddiness, shock, toothache, or sea-sickness, the best results may be looked for by giving nitro-glycerine. The regulating effect of the drug exercises an influence over the congestion of internal organs similar to that brought about by blood-letting; and in these congestions, whether of lung, brain, or kidney, when they are of a temporary character, the pulse is generally found to be slow and of low tension—a fact which, as the author remarks, is sufficiently well known in reference to the fever-free periods of acute hyperemia of the lungs.

The Method of Hunter.

The didactic plan adopted by the great surgeon Hunter, is well stated in a recent lecture by Mr. Wm. S. Savory. He said:

"But observe, I pray you, further, how Hunter proceeded in his work, for this is eminently characteristic of the man. He is not fond of starting propositions, which are then supported by arguments and made plain by illustrations; but his practice is to demonstrate in their order, without comment or dissertation, the facts which reveal knowledge. His habit appears to be not to say to us, 'I am convinced of this, and I will tell you why there can be no doubt about it,' but rather to place the premises before us—sometimes, it may be, with indifference, certainly without regard to effect, or any attempt at direction. His purpose appears to have been uniformly not to support a conclusion, but rather to make way for one. This, I think, is inscribed on the proudest monument of his genius—his Museum. May I ask you, only for a few moments, to look once more at it?"

This is really the best of all methods of instruction, because intellectually the most stimulating of all.

The Treatment of Phthisis by Eucalyptol.

Our foreign exchanges state that in Paris Dr. Bouveret has employed hypodermic injections of eucalyptol in the treatment of phthisis. The daily dose of the antiseptic has varied from one gramme and a half to two grammes and a half. The duration of the treatment has been from fourteen to sixteen days. Sixteen cases of phthisis were treated by this method; six of the number had fever, and the remaining ten were without fever. There was rarely any local disturbance at the site of injection. It was certain that the antiseptic was absorbed; it could be detected in the breath, but not in the urine. Albuminuria was not observed as the result of the treatment. It is very doubtful whether the number of bacilli was altered in any way by the method of treatment. Sweating, as a rule, was diminished. Its chief effect is as a balsamic preparation on the bronchial secretion, which it influences favorably.

Treatment of Hæmatoma of the Ear.

Dr. A. Lebrun, in a clinical lecture published in the new Brussels journal, *La Clinique*, says that after having tried various plans for the treatment of hæmatomas of the ear, including free opening as well as Follin's method of making a number of punctures, and having found them all very unsatisfactory, he has latterly injected iodoformed ether with complete success. For this two needles are inserted into the tumor at opposite points; through the larger one, No. 3 of Dieulafoy's aspirator, the contents are drawn off, the puncture being closed by means of iodoformed collodion. Then through the remaining needle, which is that of an ordinary hypodermic syringe, from fifteen to sixty minims of a solution of iodoform in ether, of a strength varying from 2 to 10 per cent., is introduced into the cavity of the tumor. This injection causes some pain, which, however, soon passes off. No dressing is required, and a complete cure results.

Resection of the Superior Maxillæ.

Not long since, at the Medical Society of London, Dr. Leopold Servais (of Antwerp) read a paper on Removal of both Superior Maxillæ for Large Tumors of the Face. The first case was that of a boy aged nine years, living at Wouroo, Holland. The operation was performed on October 10, 1883. The tumor had developed at the expense chiefly of the right superior maxilla. Fergusson's method of operation was adopted. The cautery was used to stanch the bleeding. The roof of the orbit, the orbital plate, the nasal process of the right superior maxillary bone, and the larger part of the malar bone, were preserved. Recovery was rapid. There has been no recurrence. The second case was that of a woman. The tumor had been slowly growing for eleven years; it was of enormous size and extremely painful. It had been treated by caustics. The tumor was successfully removed, and the patient was now completely well. The operation took five hours.

Herpes Associated with Locomotor Ataxy.

It is stated in a Lisbon journal that there is now in the wards of a hospital in that city a patient suffering from locomotor ataxy, who, in addition to joint affections as described by Charcot, and loosening of the teeth while quite sound, has developed herpes zoster, extending from the cervical to the lumbar region, the eruption spreading outwards in the directions of the intercostal spaces, and being accompanied by severe neuralgia and hyperæsthesia of the skin over all the region affected. A few previous cases of herpes associated with locomotor ataxy have been mentioned by Fournier, Charcot, Buzzard, and by Portalier in his thesis (Paris, 1884). In all these, however, the herpes seems to have been developed in the preataxic period. Similarly as to the falling out of the teeth, which is also rare, Fournier only mentions one instance, and in this it occurred before the manifestation of ataxic symptoms.

Hydrastis in Uterine Hemorrhage.

Dr. L. Góth has employed the tincture and fluid extract of hydrastis canadensis in various forms of uterine hemorrhage, especially in disordered menstruation, metrorrhagia, hemorrhage following abortion, and that occurring at the change of life. The best results were obtained where no organic disease existed, and in the climacteric hemorrhages. Less satisfactory effects were observed in the menorrhagia of chronic metritis, and no effect at all was produced on hemorrhage due to erosion of the os uteri, or on the secondary hemorrhage following abortions. The dose of the fluid extract used was twenty drops, and this amount was given several times a day.

The New Combination, Bismuth Sub-Iodide.

This is intended to replace iodoform. Iodine fused with bismuth forms bismuth

iodide. Boiling the latter with water leads to the precipitation of the sub-iodide as a fine powder. It, like iodol, is said to be inodorous, and yet to be equally as effective as iodoform as an antiseptic.

CORRESPONDENCE.

The Substitution Question.

EDS. MED. AND SURG. REPORTER:

In your valuable paper of February 26, 1887, there is an article on "Substitution by Druggists" that I wish to reply to, both as a physician and pharmacist; not with any spirit of envy whatever for any one, but with *candor* and *charity*. I wish to be candid with my brother M. D.'s and charitable to all my fellow-druggists—both wholesale and pharmaceutical chemists. First, let me say that I am both a physician and pharmacist. My experience began behind the counter some twenty years ago, and my time has been devoted to my profession ever since. I say this not with any disposition to egotism, but to make plain the fact that I have a right to talk. There are very few weeks but what a pharmacist meets with many little errors on the part of his medical friends, which he (the pharmacist) must correct, and that very often without consulting any one or anything except it be his own good judgment; for the doctor in question may be miles away when the prescription is presented to be filled. I might give you many illustrations as to what I say, but knowing the M. D.'s in our land to be quick at perceiving, as a rule, I will only give two to make my point clear.

Case No. 1.—For Mr. W. No. 1.

℞. Syr. ferri iod., ℥ ij.
Syr. simpl., q. s. ℥ ij. M.
Sig.—Apply with a brush.

Dr. Z.

For Mr. W. No. 2.

℞. Tr. iodine,
Glycerine, āā ℥ j. M.
Sig.—Twenty drops after each meal in water.

Dr. Z.

Now, both of these prescriptions were for Mr. W., who presented them. Dr. Z., his physician, is a good, honest, intelligent physician—rather above the average. I put up the prescriptions just as ordered, with this exception, viz., I put No. 1 direction on No. 2, and No. 2 on No. 1. Two days after, the doctor was interviewed by myself, and his prescriptions shown him. He very frankly acknowledged his mistake, which I had corrected. Mr. W. in this case knew nothing of the little mistake; for above all, the doctor and druggist should learn to keep their own secrets.

Case No. 1.—Mrs. I.

℞. Blank & Co.'s gr. ¼ podophyl. pills No. xx.
Sig.—1 daily.

Dr. O.

The young physician in this case (Dr. O.) was not well acquainted with me then. He had graduated two years before, and as yet was without much experience as a practicing physician, and less with manufacturing chemists. However, his diploma had been granted him upon merit alone, and he was certainly competent to treat the lady and her trouble in question. After Mrs. I. had handed me the prescription, I frankly told her we did not have Blank & Co.'s ¼ gr. G. C. podophyllin pills, but we did have ¼ gr. G. C. podophyllin pills, made by a party who had an experience of twenty-five years, and that we had found them to be reliable in every way, and if she said so we would fill the prescription as she ordered. She so ordered, and we filled it. I met this young doctor a few days after, and told him what we did, also gave him some good wholesome advice, which I promised not to mention. The doctor and I are perfectly good friends to-day, and he enjoys a good, lucrative practice.

The pharmacist should keep U. S. P. preparations, chemicals, etc., that he has put to the test and knows to be good. Purity and virtue should be above the name of any firm, and bribes.

Speculators in "specific" preparations should be discountenanced by all reliable physicians and druggists. Laws in regard to the manufacturing of pharmaceutical preparations should be more exacting. There is hardly a year but what some new manufacturing concern floods the country with samples of worthless articles. and begs of physicians to prescribe them. The chemicals that I keep in my case are not those which are sent me in "sample" lots, but those which I have found to be reliable by actual test. No M. D., wholesale house, or pharmaceutical chemist, can shake my confidence in a preparation or chemical that I have used for twenty years, and from which the results have been satisfactory. This I say with respect for every one engaged in the handling of medicines. Within my reach now I see eleven different catalogues of manufacturing chemists, each of whom makes two hundred or three hundred different preparations. They may all be good; but that

a retail druggist should be expected to keep some of each and all, is both unnecessary and unwise. So I for one will tell my customers the truth when I have not got what is called for, and will also give them the reason why. Very truly, H. Y. L.

St. Charles, Ills.

A Case of Spontaneous Cure of Hernia with Incidental Loss of a Testicle.

Eds. Med. and Surg. Reporter:

I was consulted by a worthy couple recently for an opinion as to the reason of their not being the parents of a family. The wife stated that they had been married five years, and, as she said, "it was about time for them to have a baby." She generously assumed the blame, and submitted to a physical examination, which exhibited a model uterus and appendages. Organically, she was not less a model than functionally. I suggested to her that her sterility was not her fault, and that an examination of her husband might throw more light on the dark subject. She sent him to me, and in his person he presented a large, muscular, well-fed, and apparently a perfect man. He denied ever having had gonorrhœa or any venereal disease; said that he "reckoned" he enjoyed connection as well as any body; in fact, took "right smart" comfort out of it. Questioning rather closely, I drew out of him the information that when eighteen years old (he is now thirty-three) he was ruptured; that for a while he wore a truss, but at last he was unable to get one which he could wear comfortably, and took to wearing a suspensory bandage. Then he took sick with cramps, which lasted for three days. All this time he had no doctor. When his cramps were gone, so also was his rupture, and with it his testicle. Since that time his belly has been "as hard as a rock." And, in fact, below the umbilicus his abdominal walls *are* hard —will not yield to the fingers or to any pressure brought to bear on them. As my object in reporting this case is to get information, I will not present any theory as to what this hardness is. I would be glad to see reported in your columns any cases similar to this. The points of interest to me are the following:

1. The spontaneous cure of the hernia. My library is entirely silent on such an occurrence. I knew one case in the earliest year of my practice, but never reported it.

2. The ascent of the testicle. If such a cure of hernia is not rare, the withdrawal of the testicle certainly is. In this connection, I will say that the same day in which this patient presented himself there came an old man with an enlarged prostate, who stated that when twenty years old he had the mumps, with the result of complete atrophy of one testicle, but he has since become the father of a numerous family.

3. The peculiar condition of the abdominal walls; what causes it? and of what prognostic value is it in regard to any possible future acute disease which the patient may contract?

4. The sterility; for it must be the result of this lost testicle. The testicle is not destroyed, but must lie imbedded in the abdominal cavity and fixed there by adhesions. The patient has now, and has had for thirteen years, perfect health almost.

A report of any cases bearing on any one of these points would, to me at least, be of extreme interest.

W. W. Claybaugh, M. D.

Gordon, Nebraska.

Long Retention of Placenta in a Case of Abortion.

Eds. Med. and Surg. Reporter:

Mrs. ———, æt. 30, mother of two children, her temperature sanguine, stature small, health usually very good, cheerful disposition, a farmer's wife, sent for me in haste, February 18, 1887. Two days prior her husband came asking a prescription for an excessive menstrual discharge, and gave the following history of her case, viz: About the middle of July, 1886, she menstruated, and did not do so again until November 7—about four months—when again the discharge appeared in what seemed to be a normal manner and quantity. During the course of these four months she had all the signs of pregnancy common with her, as absent menses, morning vomiting, enlargement of the mammary glands, increase of flesh, and enlarged abdomen. However, from the time the menses appeared in November these signs rapidly disappeared, and there were no further indications of pregnancy, except that the menstrual discharge did not return regularly. On the 16th of February, 1887, however, while lifting a crock of milk, she noticed a very free gush from the vagina, which, upon examination, she found to be blood. This soon saturated her clothing and a number of napkins, and then ceased, almost entirely without any pain worthy of note. She distinctly noted a slight chill and a sensation of coldness in the hypogastrium. I warned the husband that very probably

his wife was having an abortion, and to let me know promptly if the discharge returned; in the meantime she should keep quiet, and avoid all physical effort. Ordered ergot to be used if the hemorrhage should return. At about 1 a. m. on the 18th, I saw her, to relieve a second attack of "flooding." The discharge was not and had not been very excessive at this time, but there were present regular uterine contractions. The taxis revealed a loose foreign body lodged in the os uteri, which on removal was found to be the head of a fœtus of apparently about three months' gestation, and so friable as to hardly hold together under very slight pressure. The placenta was still retained high up in the uterus, but was loose and detached. After some efforts to extract it, and failing, I ordered ergot freely for several doses, and lay down until 5 a. m., at which time I found it lodged against the inner portion of the os, and extracted it. I found it to be hard, smooth, white, tough, the cotyledons well marked, and having no sign of any recent attachment to the uterine surface except a small margin at its inferior section, where it it was red and vascular.

The history of this case led me to believe that the pregnancy had gone on normally until the time of menstruation in November, and that the fœtus lost its vitality at that time, and had been retained ever since, the placenta being but partially attached after that date up to the time of its delivery. The partial attachment was sufficient to maintain a low degree of vitality in the placental mass, but not in the fœtus. There were no present evidences of decomposition. The portion of fœtus removed seemed more as if it had gone through a process of desiccation rather than of decomposition. The placental mass was unusually tough and hard, and light in its color.

It is not uncommon for the placenta to be retained for one or two weeks, and then be cast off as a fetid mass, accompanied generally with considerable exhausting hemorrhage. If my explanation of the clinical history of this case is correct, it is at least—though by no means unique—a quite unusual case.

In another case coming under my notice, the lady had a free menstrual flow, as she supposed, for which she was treated at the time by her physician. Six weeks later, while doing her washing, she, with little pain or hemorrhage, cast a hard, tough, placental mass. She had, I believe, not suspected her pregnancy at all. T. C. Smith, M. D.

News and Miscellany.

Poison Accidentally Ends the Life of a Baltimore Society Man.

Addis Emmet Carr, the grandson of Mr. David Dudley Field and of the late Dr. J. Marion Sims, of New York, died at his home in Baltimore, March 1, under exceptionally tragic circumstances.

Mr. Carr, who was a young man, considerably under 30, was by profession a civil engineer, and took deep interest in electrical matters and chemistry, and a laboratory was fitted up near to his bed-room. Early in the evening he was engaged in his favorite study, when the ladies of his family were terribly frightened by his suddenly rushing into their midst and exclaiming that he had swallowed a large dose of poison. A physician was sent for immediately, and to the latter Mr. Carr related that, by some mishap, he had swallowed a mouthful of the acid used for his electrical batteries, a poison of the most deadly nature. His terrible danger, however, did not rob him of his presence of mind, and he swallowed liberal doses of hot water while waiting for the doctor. When the latter arrived, Carr was in great agony; another physician was immediately summoned in consultation, and everything was done that science could suggest for the sufferer, but he died. He did not relate how he came to make his fatal mistake.

Beats the Faith Cure.

The *Baltimore American* publishes the following under the heading: "*What the President's Patch Did.*" Parkersburg, West Virginia, December 18. Ten years ago Mrs. Ada Martin, living in a small town in Ritchie county, punctured one of her limbs so severely as to cause permanent paralysis of it and deprive her of the power of speech. During the period of her affliction she has been making crazy quilts, and endeavoring to obtain patches from prominent men. Presidents Hayes, Garfield, and Arthur sent her patches, and a day or two ago she received a patch from President Cleveland, with his compliments autographically expressed. Her pleasure at the event was so great that she jumped up suddenly, and in doing so knocked a revolver to the floor, causing it to be discharged. The ball entered her paralyzed limb, and the shock removed the paralytic effects and restored her speech. Ever since the occurrence she has had the use of her tongue, which for ten years has been silenced. The physicians say

she will have the use of her limb as soon as the bullet wound is healed." We may now expect to hear of all the deaf and dumb asylums and hospitals for the crippled and paralyzed laying in a stock of assorted revolvers for therapeutical purposes.

Wills of Medical Men.

The *Lancet* gives the following particulars regarding the estates of medical men recently deceased:

Charles Chadwick, M. D., late of Breadwater Down, Tunbridge Wells, Ken; proved on November 1. Value of the personal estate amounting to upwards of £92,000. Henry Jewell, M. D., formerly of Sidmouth, but lately of Salcombe Regis, Devon; proved at the Exeter district registry on October 18. Value of personal estate amounting to upwards of £8,000. Francis Falwasser, surgeon-major, Medical Staff Corps, late of the North Camp, Aldershot, Hants; proved on October 27. Value of the personal estate amounting to upwards of £4,000. Robert Fowler, M. D., late of 145 Bishopsgate street Without, and 12 Old Burlington street; proved on November 6. Value of the personal estate exceeding £4,000. Harvey Buchanan Holl, M. D.; proved on October 11. Value of the personal estate exceeding £3,700. Walter Somerville, M. D., formerly of Greenfield, county Lanark, N. B., but late of Harrogate; proved on October 26. Value of the personal estate in the United Kingdom amounting to over £2,000.

Inebriate Jurors.

The *Journal of Inebriety* says:

A valued correspondent vouches for the following: In a Western city an inebriate was on trial for manslaughter. The defense was insanity from alcohol. After a long trial, and deliberation of two days, the jury brought in a verdict of guilty. A new trial was granted, on the grounds that two of the jury were so much intoxicated as not to be able to decide on the verdict. It was alleged that all the jury drank, and had several free fights in the jury-room. At the close of the second trial, one of the jury had an attack of delirium tremens, and rushed for the judge to whip him. In the third trial, the jury brought in a verdict of guilty, but not responsible. This was not accepted: then they disagreed. The case was then taken into another court, where the plea of guilty was made, and the judge sentenced him for life, with a heavy fine. The defense now asks for a new trial, on the ground of the incompetency of the judge, who, it is claimed, was partially intoxicated when sentencing the prisoner.

Pasteurism in Russia.

The operations of the Russian Pasteur Institute at Odessa have proved a signal failure, says the *Buffalo M. and S. Jour.* One-third of all the patients treated have died, and it seems highly probable that some of the deaths are due solely to the treatment. The following case, from *Novoe Vremia*, will serve as an illustration: In the month of July, 1886, Dr. Arthur Stoboi was bitten by a dog supposed to be affected with rabies. The boy was immediately sent to the institute of Dr. Boniville, in Odessa, and was there treated according to the system of Pasteur. On the 9th of November he experienced a severe pain in the place where the virus had been inoculated by the physician, and, two days afterward, died of rabies. The dog which bit the boy, however, is still alive, and has, up to the present time, shown no symptoms of hydrophobia. We must thus necessarily attribute the death to the treatment alone.

A Walking Maniac.

Dr. Zenner, in a recent lecture at Cincinnati College, referred to John Snyder, of Dunkirk, whose marvellous feats of walking have interested the medical profession as well as the public. Dr. Zenner said that to him the man seemed perfectly rational, and was certainly not an impostor. During the forty-eight hours that he was watched by the students of the Ohio Medical College, he walked all but seven hours, and did not lie down at all. He says it does not rest him, but makes him tired and uncomfortable to sit down. The disease then is not in the walking, but in the uncomfortable sensation on account of which he walks. Weston walked 5,000 miles in one hundred days; but this man has walked almost 25,000 miles in five hundred days, and is no more tired than when he began. His gait was such as to cause the least possible fatigue.

A Whistling Barometer.

In the village of Meyrin (Canton of Geneva), Switzerland, some disused wells, it is said, have been hermetically sealed to serve as barometers to the people. According to the *Scientific American*, an orifice about an inch in diameter is made in the cover of the well, by which the internal air is put in com-

munication with the external When the air pressure outside diminishes on the approach of a storm, the air in the well escapes and blows a whistle in connection with the orifice, and in this way notice of a storm's approach is given to the inhabitants. If, on the contrary, the pressure increases, a different sound is produced by the entry of the air into the well, and the probability of fine weather is announced.

One of the Results of Cremation.

Miss Kate Field tells the following, illustrative of one of the benefits of cremation. A lady, visiting some friends, neglected to bring her tooth-powder. Looking about her bed-chamber she noticed an elegant vase. On removing the cover she found a grayish, calcareous powder. This she regarded as a dentifrice, and proceeded to avail herself of the discovery, finding it very satisfactory. The next day she mentioned the fact to her hostess, apologizing for making free with her tooth-powder. The countenances of the family expressed various emotions, which at last found vent in the gasp of one of the daughters, "Why, that's aunty!" Thus, as a tooth-powder, the ashes of the cremated are a success.

The Secret Remedies of Berlin.

In the list of "secret remedies" of which the Berlin police have published a series of analyses in the daily press, are the following: "Bauer's Consumption Cure" consists of a decoction of malt and apples; "Volkmann's Drunkard's Cure" is a mixture of gentian and lycopodium; "Baretta's Stomach Powder" is a mixture of bicarbonate of soda, with cream of tartar, milk, sugar, sal ammoniac, chalk, and a trace of pepsin; "Harz's Mountain Tea" consists of a mixture of peppermint, lactuca, liquorice, sassafras, lavender, and milfoil.

A Question Answered.

Professor of Physiology: "What would be the result if, when a person takes an inspiration of air, it should pass into the stomach instead of the lungs?"

Student: "It would soon become a borborygmus, and, in utter disgust, make its exit at the back door, with as much noise as if it were authorized to announce another question in physiology."

Why He Lost a Good Patient.

A prominent Philadelphia surgeon, says the Philadelphia *Medical Times*, lost a good patient, a spinster, the very pattern of propriety, by writing a prescription for "Fluid Ext. Rham. Cat." After reading the prescription, she said nothing could induce her to swallow such a remedy, and that the doctor ought to be ashamed of himself for ordering it. He is now a sadder and a wiser man, and keeps on the safe side by prescribing castor oil for his hysterical patients.

Quicksilver Production in Tuscany.

The two Italian mercury works, Rosselli and Schwarzenberg, situated at the Monte Amiata, south of Siena, yield annually from 7,000 to 8,000 bottles, about two-thirds of this quantity coming to the Rosselli works. The mercury is sent to Mr. Luigi Donegani's depot in Leghorn. and thence principally to the English market. A little antimony is also produced at the Monte Amiata.

Forty Thousand New Doctors in Ten Years

In the last nine years 103,598 persons have matriculated as medical students, and one-third of these, or 33,684, have become doctors of medicine. At this rate the total number of doctors for the decade will be nearly 40,000. For making these, the medical colleges must have received over twelve millions of dollars.

A Good Resolution.

At the recent annual meeting of the Ohio State Board of Health, Dr. Jones introduced a resolution requiring that every railroad company doing business in Ohio shall carry on its trains an emergency case, which shall contain bandages, cotton, and other things desirable in accidents, and that employes shall be instructed in their use by the surgeon of the road.

The Castor-Oil Industry in the United States.

Florida is following Louisiana in the attempt to make money out of the *Ricinus communis*. A firm in that State are preparing 320 acres to be planted in castor beans, and next year an oil mill will be erected.

Herrings Cured by Boracic Acid.

The new method of curing herrings by the application of boracic acid has proved extremely successful in Norway, and called into life quite a new industry at Bergen. There is no doubt that this discovery will in future be greatly developed.

A New Interpretation of "M. D."

The *Southern California Practitioner* is responsible for the story of a doctor who gave up his profession on account of ill-health, and went into the milk business. He printed his cards "J. B. Johnson, M. D. (which means milk distributor)." He recovered.

Dr. William Hunt Injured.

Dr. William Hunt, 1300 Spruce street, was knocked down and run over by a wagon at Broad street and Girard avenue recently. He had his right arm broken, and sustained severe cuts about the head and legs.

The Epidemic at Shenandoah.

The borough of Shenandoah is now experiencing a most terrible epidemic of measles and scarlatina, directly traceable to the filthy and generally insanitary condition of the town.

Small-pox in New York.

There were five cases of small-pox discovered in New York, March 5. The patients were removed to the hospital, and means were taken to prevent the spread of the disease.

Cholera Epidemic at Montevideo.

The Secretary of State is informed that the cholera has been officially declared epidemic at Montevideo.

Definition of Medicine by a French Scoffer.

What is medicine? The art of killing people without offending the police.

Personals.

—Dr. H. C. Wood, of this city, has been tendered the chair of medicine at the Johns Hopkins University, Baltimore.

—Dr. Brodeur, of Paris, has gone to Montreal to establish a permanent home and introduce in America the methods by which Pasteur cures or prevents hydrophobia.

—William T. Taylor, whose death is announced in the 65th year of his age, was a graduate of the University of Pennsylvania, a member of the American Medical Society, Philadelphia County Medical and Philadelphia Obstetrical Associations.

—Dr. Emmet is reported by Dr. Munford, in the *Indiana Medical Journal,* as saying that in five years every man who has spayed a woman will apologize for having done so.

Items.

—*Life* says that they do not say "stomach-ache" in Boston. They call it gastric neuralgia; but it gets there just the same.

—The distressing ear symptoms produced by the administration of quinine or salicylate of sodium are counteracted by the addition of small doses of ergot to the mixture.

—A German enquirer has, it is stated, taken four heads of hair, of equal weight, and then proceeded to count the individual hairs. One, red, was found to contain 90,000 hairs; another, black, 108,000; a third, brown, had 109,000; and the fourth, blonde, 140,000.

—The late Professor Panum, the distinguished Danish physiologist, died, in his sixty-fourth year, from thrombosis of the coronary artery, consequent fatty degeneration, softening, and finally rupture of the ventricular wall. He died literally of a "broken heart."

—Dr. Arthur Mitchell, from a large number of statistics, has come to the conclusion that illegitimacy is a very common cause of idiocy; the mental agony undergone by the mother causing an arrest of development of the embryo, giving rise to a congenital or developmental idiocy.

—A large factory of Breslau required a chimney fifty-four feet in height. Instead of constructing the chimney of bricks, as usual, a large number of solid blocks of paper, firmly compressed, were made use of. These blocks were placed carefully one on the top of the other, and joined together with a special cement.

OBITUARY NOTICE.

Joseph Wilson, M. D., U. S. N.

Dr. Joseph Wilson, Medical Director of the United States Navy, died recently in this city. Dr. Wilson was born in this state; appointed assistant surgeon May 13, 1843; served on the vessels in the Pacific Squadron until 1847; took part in the Mexican War; was attached to the store-ship supply in the Japan Expedition in 1852–55, and the Philadelphia Navy Yard until 1857.

In the latter year he was commissioned surgeon, and served on the Pacific and North Atlantic Squadrons till the outbreak of the war of the Rebellion. He participated in the capture of Port Fisher, and at the close of the war served on the Board of Naval Surgeons. In 1876 he was President of the Board of Naval Examiners.

Pallas Syringe."

W. H. SCHIEFFELIN & CO'S.
SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

GREEN SPRING SANITARIUM,
AND
WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten acres. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

BELLEVUE HOSPITAL MEDICAL COLLEGE,

CITY OF NEW YORK.

SESSIONS OF 1887-88.

The REGULAR SESSION begins on Wednesday, September 21, 1887, and ends about the middle of March, 1888. During this Session, in addition to the regular didactic lectures, two or three hours are daily allotted to clinical instruction. Attendance upon at least two regular courses of lectures is required for graduation.

The SPRING SESSION consists of recitations, clinical lectures and exercises, and didactic lectures on special subjects. This Session begins about the middle of March and continues until the middle of June. During this Session, daily recitations in all the departments are held by a corps of Examiners appointed by the Faculty.

The CARNEGIE LABORATORY is open during the collegiate year, for instruction in microscopical examinations of urine, practical demonstrations in medical and surgical pathology, and lessons in normal histology and pathology, including bacteriology.

For the annual Circular and Catalogue, giving requirements for graduation and other information, address Prof. AUSTIN FLINT, Secretary, Bellevue Hospital Medical College, foot of East 26th Street, New York City.

OCULIST AND OPTICIAN.

BY G. T. FOX, M. D.,

Of Bath, Pa.

In looking over the Reporter of recent date, I came across a communication of Drs. L. Webster Fox and George M. Gould, of Philadelphia, subject: "The Oculist, the Optician and the Public," which I read with a great deal of interest. The subject was treated entertainingly and practically, and it is the complete conviction of the truth of my experience that leads me to comment on a subject of so vital importance. We agree with the writers on this subject, that the supplying of spectacles is a function of profound importance to the community at large. Yet this office is shamefully prostituted; and how often does the thoughtful, conscientious oculist realize that the problem of the oculist's and the optician's relations deserves renewed and vigilant consideration in order that some reformative means may be devised through which evils of omission and evils of commission pertaining to the professional relations between oculist and optician may be corrected. I lay nothing at the personal door of any particular optician, but aim solely to reach some analysis of the principles on which our mutual relations are conducted, and get some periscope of the ground lying between the individual provinces of oculist and optician. And in this connection let me premise that as business men the generality of opticians excel the generality of oculists. They are enterprising gentlemen, who guard and exalt their opportunities with pious, almost Spartan fidelity, who make their profession the *medium of business*, and neglect no means that comes within their reach to advance their pecuniary interests. The optician stands on the same plane to the oculist as the druggist does to the physician. If the druggist, disloyal to the confidence and purpose of the physician, cuts off a large measure of his just support by prescribing, he is wholly outside his province. So the optician who prescribes glasses presents the impolitic virtue of surreptitiously appropriating and guillotining the oculist's income.

In taking a comprehensive glance at the inter-professional domain of oculist and optician, we perceive that the office of the oculist is peculiarly that of discerning the nature of the optical defect of his patient, and directing orally or by prescription, indicating the kind of lenses proper for the relief and restoration of vision; while professionally, it is the office of the mechanical optician to grind the lenses as ordered by the oculist.

In our country towns our jewelers do quite a large trade in selling spectacles; but I must say this to the credit of a number of jewelers—that if they meet with cases that they don't well succeed in fitting with glasses, and suspect refractive errors, they will invariably send them to me for correction. There is no class of men that does more injury to the eyes of the public than these traveling oculists, or better, charlatans and impostors, who go from house to house selling spectacles. We have had them travel through this and neighboring counties. They are always foreigners; style themselves "Prof.," put on a commanding air. They have not the slightest knowledge of the theory of optics

or the mechanical process by which a lens is made; but by a voluminous flow of gibberish they overpower their victims and tell them "Zur, you spile your eyes mit dem spectacle you wear; you youst dry dis ones." Here, in all probability, a higher-power lens is handed. "Don't you see better? Dem be de finist Brazilian bebbles; I grinds dem myself in my factory." And thus by lying they get from five to ten times as much as these spectacles are worth; and nine times out of ten the buyer finds out when it is too late that he has been imposed on and cannot wear the glasses. Only last week a party came to my office and told me how he had been imposed on by such an itinerant rascal, paying him $12 for spectacles that are not worth $1 to him. I told him it served him right. I know of a half dozen parties in this neighborhood that have paid in the aggregate between $75 and $100 for spectacles to an itinerant oculist—a "Prof.," of course—and I am told by good authority that they all confess they are no good. One of these traveling impostors had the impudence to use my name, stating that he furnished me with all the glasses I prescribe; but this was disbelieved by a great many where he made these unwarrantable assertions.

If time would permit, I could cite a number of cases similar to the one of Dr. Fox, of Philadelphia, when the selection of glasses by the patients themselves proved detrimental to vision; but our limited space forbids it, and I will refer to one case in our town, where a lady made her own selection. She suffered a great deal from neuralgic pains, as was supposed, for which she was treated at various intervals. The presbyopia increased; again a change in glasses was made, which only gave temporary benefit. At last one of these traveling impostors, with his unwarantable pretensions as to skill, promised a speedy cure for her optical defect. But alas! the pain would return, and the dimness of vision increased. She then applied to me for relief, but I was obliged to tell her that the time for relief was wasted. She had chronic glaucoma, and sight now is irrevocably lost.

We cannot leave this subject without referring to the valuable paper that was read before the Baltimore Academy of Medicine by J. J. Chisholm, M. D., and published in the same number of the MED. AND SURG. REPORTER, subject: "Rest for Painful Eyes—Is this Always Good Advice?" I have no personal acquaintance with Dr. Chisholm, but have known him by reputation for a number of years, and have had the pleasure of communicating with him on subjects pertaining to ophthalmic and aural surgery, and his answers to my queries have always been very much appreciated, imparting sound practical advice. Every medical practitioner is constantly meeting with cases such as are described in Dr. Chisholm's paper, where there is sufficient suffering and impairment of working power of the eyes to demand serious attention. Headache due to eye-strain is very common, and the doctor's statement that "headaches which come on with the use of the eyes, and which disappear during the rest which a night's sleep brings to the weary eyes, do not usually depend on gastric, hepatic, cerebral or uterine troubles, as is commonly believed," is the complete conviction of the truth of my experience. I have time and again satisfied patients that their brains, stomachs, livers, kidneys, or uteri were healthy, and the cause of their headaches was due to faulty refraction, and by giving them properly selected glasses I cured these headaches from which they had suffered for years, and which naturally would defy all manner of medical treatment. I can perhaps in no way better illustrate this than by citing my own case. I had always been a great sufferer in my head from my youth up, with frequent attacks of conjunctivitis and blepharitis ciliaris, which began to form in early years, which always became aggravated when I used my eyes in study. Riding in the cars a dozen miles would bring on a violent attack of sick headache, with retching and vomiting, so that I was obliged to take to my bed, which was always looked upon as a gastric and hepatic disturbance, and I would take medicine accordingly; but the headaches would return again and again, and especially when I would exert my eyes by long and continued study. Being almost reconciled to the inevitable, expecting to remain a victim of headaches for life, I came across an article published by my friend, Dr. P. D. Keyser, of Philadelphia, some ten years ago, "On Defects in Refraction and Accommodation." This to my mind clearly pointed out the origin of my case, and led me to an examination of my eyes, and I found that I had faulty refraction from astigmatism. It is now ten years since I began to wear glasses; the blepharitis ciliaris is cured, the headaches are eradicated and bygone, only to be remembered from the years of torture through which I passed. I now travel on an average from 500 to 800 miles every month by rail, but no return of headaches. Nothing but

the careful adjustment of minus cylindrical glasses has cured me.

It would be the height of folly for the specialist to attribute all the ills of humanity to a derangement of the organs which he has made a study, and no one who has sound knowledge and practical experience will pursue such a course; he knows the bond of sympathy between every organ of the body; he knows of the many and varied reflex troubles that we have to contend with; and if I hear of a specialist that attributes all ills to the special organ which he makes a study, I consider him a fanatic, a bane of modern medicine, and my advice would be, let him alone severely. In taking a glance at ophthalmic surgery, and especially the subject of refraction as rationally practiced, when contrasted with the stereotyped course as followed by many physicians, many deductions may be drawn. We not only find much to learn, but much to unlearn. I have not attained, nor do I expect, the amount of success of those who practice their chosen specialty exclusively. Yet I have the gratification to see some evidence at least that my labors have not been in vain. And the surest way of gaining that end is by studying and paying due respect to the rules, methods, and precepts of the acknowledged "lights" in these special branches of medicine. In this age of diffusion of medical knowledge—by means of the medical journals—many physicians are on the alert to distinguish eye headaches from the headaches due to other organic disturbances, and usually invoke the aid of the oculist to remedy the evil. But there are others in the profession who are "wise in their own conceit," who will accuse the specialist of being "*novitatis potius quam veri studiosus*," but it must be borne in mind that the medical art is progressive. Science seems to be on the verge of letting in the dawn of a new day, and the readers of our valuable MEDICAL AND SURGICAL REPORTER are catching the rays transmitted and thrown off by these "special lights," thereby receiving constantly useful information, and through this reading become better qualified to perform the duties of the profession. Therefore, let the men engaged in special branches of medicine make their experience, their methods, and plans of treatment, known through journals for the benefit of their professional brethren, who, feeling the greatness of their mission, labor for the welfare of mankind. There is much to learn, and there yet remains very much land to be possessed in the work of original investigation; and this applies to all branches of medicine. Hence, let the physicians who have had the opportunity of noting the progress in medicine, who have observing minds and mature judgment, who show, as their years increase, their activity and professional enthusiasm does not diminish—let them keep their pens in motion. What they write has weight; it is always acceptable. And the physician who reads medical journals with regularity is always furnished with some new hints, and thus keeps abreast of medical progress. We are always learners, and find that much needs to be supplemented both in knowledge and experience to become master of the science and expert manipulators of the art. "Work, watch, and wait," should be every physician's motto, and be satisfied with no attainments, however high. The *ultima thule* lies beyond.

THE PRACTICE OF MEDICINE BY THE CHINESE IN AMERICA.

BY STEWART CULIN,

Of Philadelphia.

Many of the Chinese stores in our American cities keep a supply of Chinese drugs, and all of them sell Chinese proprietary medicines, such as pills to aid digestion, the "red pills," * *Shá hi ün* † for cholera, catarrh snuff, and other specifics compounded in the Canton drug shops. These are always neatly packed and labeled, and accompanied with printed directions for their use.

But there is often a regular drug business, usually carried on by a separate company, in the stores, and a supply of drugs comprising many, if not all, of those called for in their practice, contained in numerous boxes and drawers on one side of their shops. Here, often, a Chinese doctor, usually some poor and broken-down student, who ekes out a living by assisting at the drainings of the lottery, has his office.

With a desire to learn something of the method of treatment and obtain some practical knowledge of the Chinese *materia medica*, I recently called upon a doctor connected

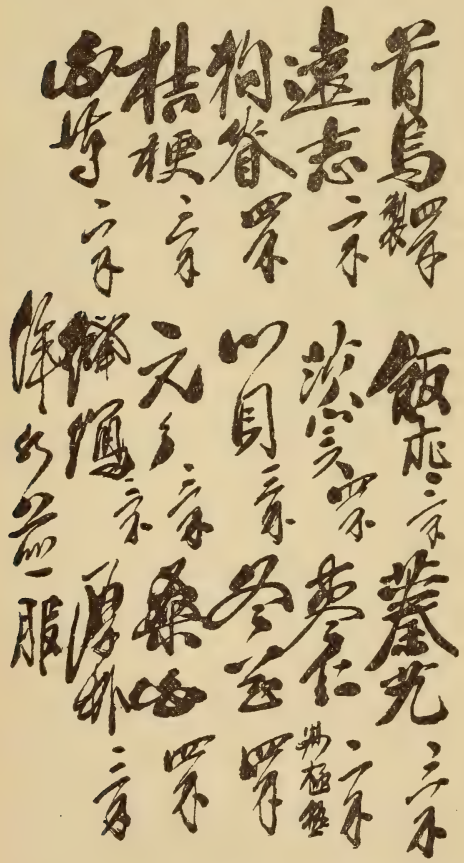
* The red pills, *shá hi ün*, spoken of by the Abbé Huc and other travelers, are highly esteemed among the Chinese here as a specific for diarrhœa and bowel complaints. Their entire composition is a secret, but they are known to contain calomel and the aromatic root of a water plant, *she hêung*.

A ball of earth called *shim sü*, "toad butter," which the toad carries in his mouth during the dry time in autumn (sic), is reputed to form an active ingredient in the *shá hi ün*. They are said to lose their virtues after being kept longer than a year.

† In the absence of Chinese type, the Chinese words are rendered in the English equivalents of the Canton dialect, according to S. Wells Williams.

with one of the principal Chinese stores in Philadelphia, and requested him to prescribe for a cold on the chest from which I was suffering.

The doctor was a pleasant-mannered man of about forty years of age. Resting my hand upon a book, he carefully felt my pulse, first on the left wrist and then on the right, delicately compressing the artery and gradually relaxing the pressure. Then, without inquiring about the symptoms of my complaint, he wrote the prescription, a fac simile of which is herewith reproduced. The fifteen medicines called for are all of vegetable origin. The following transcription of their names, with some notes on their properties, and the quantities indicated in the prescription, may not be without interest.*



Shau wu (a root highly valued as an aphrosidiac, said to have received its name fron Ho Shau Wu, a resident of Szechnen, who lived unmarried until the age of 54 years, when he discovered the peculiar qualities of this root. He then married and had several children, and his life was prolonged by its use to the ripe age of 110 years). 4 *ts' ín* (15.08 grams.)

Un chi (a root from Szechuen, a tonic), 2 *ts' ín* (7.54 grams).

Kau chaok (a plant of hair at crown of root from Fukien province) 4 *ts' ín* (15.08 grams).

Kat kang (belwort, root of the *Platycodon grandiflorum*, a tonic and stomachic), 3 *ts' ín* (11.31 grams).

Pak cheuk (root of *Pœnia albiflora*, a tonic, sedative, and alterative), 2 *ts' ín* (7.54 grams).

Pak shut (a sweetish sort of root; a tonic much valued as an aid to digestion; from Chêhkiang province), 2 *ts' ín* (7.54 grams).

Ts' z' shat (the seeds of the *Euryale ferox*; a tonic; from Kiang-su province), 4 *ts' ín* (15.08 grams).

Ch' ün pui (a demulcent; from Szechuen province), 3 *ts' ín* (11.31 grams).

Ün ts' am (a root used to check internal hemorrhage and for coughs and colds; from Chêh kiang province), 3 *ts' ín* (11.31 grams).

Chák sé (a root taken for diseases of the kidneys, as its name implies, a diuretic), 3 *ts' ín* (11.31 grams).

Ts' un k' au (dried roots of the *Gendarussa*, given in cases of rheumatism and fever), 3 *ts' ín* (11.31 grams).

Tsò yan (seeds of a species of *Rhamnus*, probably the *Rhamnus soporiferus*, a soporific), 2 *ts' ín* (7.54 grams).

Tung fa, "Winter flower" (flowers of a plant resembling the chrysanthemum) 4 *ts' ín* (15.08 grams).

Song pak (the white skin from the roots of the mulberry tree), 4 *ts' ín* (15.08 grams).

Hau p'ok, "thick bark" (the bark of a tree from Szechnen), 3 *ts' ín* (11.31 grams).

A clerk in the store weighed out the different articles with a small Chinese balance, and deposited them together on a piece of paper, first powdering the *ch' ün pui* in an iron mortar, and roasting the *tsò yan* in a pan; the *pak cheuk* was moistened with whisky before being placed with the mass. All was then put in a pot with four large cups full of cold water, and boiled for half an hour. The decoction I was enjoined to drink warm before going to bed.

Should this medicine have failed to relieve me, the doctor, upon my next visit, would have varied his prescription. The charge for the medicine was fifty cents, the

*The writer is indebted to the Catalogue of the Chinese Imperial Maritime Customs Collection at the United States International Exhibition, 1876, *Shanghai*, 1876, for much of the information used in preparing these notes.

price of each ingredient being computed separately. The doctor's fee was one dollar, this being the usual charge for each consultation. Their expenses are paid when they make visits at a distance.

The doctors, called *í shang*, of whom there are now four in Philadelphia, are usually from the *Sam Yap*, or "Three Districts," immediately adjacent to Canton city. They are much better educated than the mass of the people. None of any repute at home come to America, but it is said there are several very skillful ones in San Francisco and some of the western cities, who have a large practice among Americans. Those in New York and Philadelphia rank very low in their profession, in the estimation of their countrymen. They are all dignified with the title of *sin shang*, equivalent to master or teacher, the only title of respect current among the Chinese in the American cities, and shared with the men who manage the drawings of the lotteries.

A slight knowledge of medicine is general among the people. They have been accustomed to take medicines from their childhood, when their mothers, by a kind of sortilege, selected some simple prescription to relieve their infantile complaints. The study of the physician's art is not confined to their doctors. Many others buy and read works on the subject that are sold in their stores, in which very exact directions are given for the treatment of all the diseases known to them.

The book generally referred to is the *Tsung e kam kám*, or "The Golden Mirror of Medicine," a collection of medical works compiled by order of the Emperor Kienlung, in 1740. The Canton reprint sold here is contained in forty small octavo volumes, the first thirty of which are devoted to *nui fo*, or "internal medicine," while the remaining ten comprise the *Kam kám ngoi fo*, or "Golden Mirror of External Practice," by 'Ng Him. The price of the complete set here is about $2.25.

While the Chinese in our eastern cities are superstitious, and cherish many of their native beliefs, they do not worship any particular god of medicine, and the practice of medicine among them is comparatively free from superstitious observances. Sick people sometimes burn copies of the charms found in the popular works on divination and magic, and drink tea made from the ashes, but this is done with very little serious belief in the efficacy of such treatment.

In cases of prolonged illness, a friend of the sick person is sometimes sent to the local shrine of Kwan tai, the divinity generally worshiped, to burn incense and ask the will of heaven as to his recovery by throwing the divining sticks.

Diseases which do not succumb to the treatment after being correctly diagnosed and the right medicine administered, are looked upon as due to the influence of a spirit or devil. Hysteria is generally regarded as an evidence of demoniac possession.

The people as a class are very healthy; venereal diseases and the complaints resulting from an excessive use of opium are the most common. They call upon their own doctors when ill, but are much averse to taking foreign medicines or submitting to the treatment prescribed by American physicians. They regard opium as a specific for colds and many complaints, and in slight disorders resort to their pipe before consulting a doctor. Chinese ginseng is highly valued for its supposed strengthening and life prolonging qualities (it is not looked upon as an aphrodisiac), and is taken in the form of pills or made into a tea by many of the older men in the spring of the year. American ginseng is seldom if ever used here.

Calomel is prescribed in syphilitic diseases. Quinine is known as *kam kai náp*, doubtless a Chinese transcription of *cinchona* and that sold in their stores is imported from China. It is prescribed for violent chills, and is looked upon as a very strong and dangerous medicine. With a few exceptions, mineral remedies are seldom employed, and roots, barks, and herbs, administered in the form of teas, constitute the principal drugs used. Many of these are not regarded as possessing any particular virtues, and some are retained solely through a tradition of cures once effected by them. Custom has ordained that a prescription shall contain a number of ingredients, of which, may be, two or three only are considered to have any direct effect.

The doctors show much solicitude about administering any medicine that may cause a fatal result, owing, no doubt, to the penalties inflicted in China upon such misadventures, so that their treatment in general, if not beneficial, does no particular harm to their patients.

—An Iowa quack told the Iowa State Board of Examiners that strychnine was the solid extract of belladonna, and that the dose was two to five drops. He has practiced in Nebraska for three years. Another told the Missouri State Board of Pharmacy that brucine was obtained from opium.

SOME RECENT STUDIES AND OBSERVATIONS ON TINNITUS AURIUM.

BY LAURENCE TURNBULL, M. D., PH. G.,

Aural Surgeon Jefferson Medical College Hospital, Phila.

(*Continued from page* 35.)

Tinnitus the Result of Diffused Desquamative and Furunculous Inflammation of the Auditory Meatus and Drum Membrane. See a list of cases in our manual, page 466, new edition.

Hypertrophic Disease of the Middle Ear as Cause of Tinnitus Aurium, and its Treatment by Nitrite of Amyl.—Dr. Alt reports some favorable cases of tinnitus aurium treated by this agent, D. J. Michel, of Hamburg, employed this remedy as early as 1877, in twenty-five cases, and Dr. Urbantschelich, still later, in six cases. More or less improvement occurred in twenty-one cases, but only in three did the tinnitus disappear entirely from one ear. From one to five drops of the remedy was inhaled at a sitting.* We have employed this agent since 1878 in various forms of tinnitus, especially the cases of hypertrophic changes in the middle ear, and in affections of the labyrinth, as recommended by "Michel." A few were benefited, but the majority were not improved, and in none was there a permanent cure by it alone, *i. e.*, pure and simple.

"Tinnitus Aurium" Due to the Excessive Use of Tobacco.—If tobacco, in its moderate use, causes tinnitus aurium, or deafness, what an immense number of persons would be deaf or troubled with noises from this cause! As before stated, however, the excessive use of tobacco exercises a deleterious influence on the heart, and by reflex irritation on the eye and ear.

There are a certain number of persons who have catarrhal and middle-ear deafness from cold, and the noises which accompany it. These persons suffer much more when they indulge in the excessive use of tobacco, and especially is this the case when smoking out of doors is indulged in. There are other individuals who, when they smoke a single strong cigar, will have functional disturbance of the heart, with increase of the pulse, and irregular action of the heart with noises in the ears. The only effectual cure is for them to give up the use of tobacco absolutely, and be properly treated for catarrhal inflammation of the ear, throat, etc.

The Influence of Aural Diseases Upon Nervous and Mental Disorders.—The neurologists and psychologists do not estimate the importance of this subject, or give it due attention in their examinations. The essay* is a "condensed resumé" of the pertinent literature of the subject, and dwells on the importance of the subject. He reports a case of a man about fifty years of age, an enterprising, moral, sober-minded person, a successful merchant, who had enjoyed uninterrupted good health previous to the accession of the persistent and "peace-destroying" tinnitus which caused him to abandon his business and give up family and friends; but in all his wanderings over the world he was still pursued by his tormentors, and finally shot himself the night after he had consulted with Dr. Catlett, who is unable to report whether his hallucinations had any association with aural disease, as he was unable to examine the condition of his ears. He concludes with the following observations on a case of insanity, which if not caused by, was increased and maintained by aural disease: The disease was obstruction from old purulent discharge from both ears with perforations of the membrana tympani: "Daniel J. H——, admitted into the asylum October, 1882, aged twenty-one years, single, occupation a farmer. He has been a man of good moral habits, except somewhat addicted to masturbation. He has had aural inflammation in both ears as the result of scarlatina since he was eighteen years old, and had a discharge of matter from both ears since that time. First attack, duration an indefinite period, as he has been eccentric for some years. His insane peculiarities are confined to his peculiar restlessness and constant circular motions, walking round in a circle to the right. He has tinnitus aurium, hears persons conversing with him, frequently looks out of the window to see who the persons are whom he hears talking, etc. The paternal aunt was insane. No other history of heredity. He suffers from insomnia, but eats well; is self-willed and perverse. He is suspicious of persons, and is fearful of personal injury. He is very obstinate, and refuses to comply with the requests of the physician and attendants; was compelled to restrain him to examine and treat his ears. Found both auditory canals filled with hardened, dried pus.

When the obstructions were removed, found both drum-heads perforated, and a purulent discharge from the middle ears. Both Eustachian tubes were free, as bubbles of fluid could be seen escaping through the

*Turnbull, Manual of Anæsthesia, second edition, pages 133-4.

*American Journal Insane, 1884, 5 xli., 275, by the late George Catlett, M. D., St. Joseph, Mo.

ears when air was forced through the tubes. Hearing improved, and the auditory sound diminished, and the hallucinations became less; also the disposition to keep in motion either in the right circular direction or otherwise as the disease in the ears improved. Without further details of the case, it is satisfactory to state that this man returned home in four months sane, and apparently well of his aural disease.

There are some forms which in time, if neglected, become almost a mental malady if the brain is diseased or if there is a hereditary tendency in the family to insanity; but we have never known a case of suicide from this cause, and our opinion is confirmed by the late Dr. Kirkbride, who for so many years was the physician-in-chief of the Pennsylvania Hospital for the Insane, Philadelphia, expressed in a letter to the writer: "I do not recall a case of insanity really owing to aural disease, although I think that defective hearing often aggravates some of the delusions of the insane, and disorder of the hearing apparatus is not frequent in insanity."

Dr. J. H. Worthington, physician-in-chief of the Friends' Asylum for the Insane, Twenty-third ward, Philadelphia, thus writes: "I never knew a case of mental disorder which owed its existence to such disease (aural), nor any case of suicide in consequence of tinnitus aurium."

A similar opinion is expressed by Dr. John Curwen, chief physician of the Pennsylvania State Lunatic Hospital, Harrisburg, who had also a long experience as first assistant.

I can find but only two or three deaths in tens of thousands of cases. As tinnitus aurium is one of the chief symptoms of acute and chronic catarrh of the middle ear, it is no wonder that in the immense number of such cases seen by the numerous specialists all over the world, that the brain may have become affected in those few cases and disturbed the reason of a weak person. Even to inform such a one "*that he would not get any relief from this very trying symptom,*" is itself almost sufficient to produce the result. So far as we are informed, there was no diagnosis in one or two of the cases as to the disease being simply of the middle ear or the labyrinth and brain, by the method whether a tuning-fork was heard louder in air or through the bones of the head.

Dr. C. E. Wright published a case under the care of Dr. Parr, in the Indiana State Asylum for the Insane, who placed a steel button in her ear (as children often do). Several ineffectual attempts were made to extract it while in the asylum, but in spite of it the patient recovered her sanity. She was termed cured. For a year and a half it constantly annoyed her, but produced no symptom of insanity. Her friends fearing a return of the mania (which of itself was not the cause), Dr. Parr sent her to Dr. Wright, who removed it under the influence of an anæsthetic. This confirms our own examinations and correspondence, and gives a more hopeful and proper view of even the worst form of this affection.

Our rule should be that if there is any hereditary tendency to mental disease, and there are persistent hallucinations resembling any of the forms we have given as examples, care should be taken that the ears be examined, and, if it be possible, this symptom removed.

Always endeavor to encourage the patient by suggesting that an improvement may occur by varying the treatment, and also by being able to state that the brain or auditory nerve is seldom involved, and that as a rule it depends in the great majority of instances on some slight change in the muscles, ligaments, or blood-vessels of the middle ear, which may cause increased pressure in the labyrinth. Hundreds of such cases are relieved by simply removing the offending cause.

*Tinnitus Aurium Produced by Aneurismal Dilatation of the Left Posterior Auricular Artery.**—We have had two cases of this form of tinnitus. In both there was a peculiar whistling and puffing sound (aneurismal thrill), caused by aneurism of the temporal branch of the internal carotid artery. In a third case reported the artery was tied with success. According to Hyrtl, there is in man a capillary which passes to the promontory. Might not affections of the tympanum frequently induce alterations in this vessel? Patients are sometimes relieved of pulsatile sounds by compression of the external carotid. The application of the continuous electric current is beneficial, particularly in passive congestion from vascular atony; it excites contractility, and causes blood stasis to disappear.

Subjective Tinnitus Occurring in Hysteria, and the Hysterical Element in Aural Diseases.—There are unquestionably numerous cases in which the subjective symptoms

* In some cases there is tinnitus aurium without its being a precursor of deafness. This is te med nervous tinnitus, and is found in several instances. The tinnitus disappears, leaving the hearing as good as ever. Especially is this the case in nervous ladies. See cases reported at end of this series of papers.

of an existing aural disease are increased to an extent which gives them undue importance in the mind of the practitioner by the co-existence of functional cerebral disturbance, evidencing itself in the train of symptoms to which, collectively, we give the name of hysteria.

Forms of Tinnitus the Intensity of which is Increased by the Action of External Sounds.—The tinnitus is produced by repeated prolonged exposure to sounds, as in the case of musicians, amateurs, and artisans of various crafts, as before stated. Means should be adopted to shield this class of patients from the action of external sounds.

In those cases, also, where aural disturbances are attributable to a sudden violent concussion, and in which the tinnitus is not aggravated by external sounds, in connection with an existing impairment of hearing and great sensitiveness to certain sounds, a strict adherence to the above-mentioned regime will often produce improvement in hearing and amelioration of the tinnitus. Both Urbantschelich and the author have noted the observations that in many cases of subjective tinnitus the application of a vibrating tuning-fork or small wheel, or the breaking of an electric current, will frequently produce a marked temporary amelioration, occasionally an entire suspension of the symptoms. In a case of tinnitus of a high-pitched, whistling character, caused by the low rumbling of a vehicle like the locomotive, improvement is secured by methodical treatment of using objective sounds opposite in pitch to that of the subjective tinnitus. Tinnitus high in pitch, such as hissing or ringing, is to be treated by low tones (C_1 C), while inversely, low, rushing, and roaring tinnitus by objective tones high in pitch (C_3 C_4).

In many cases this treatment was followed by an immediate or gradual improvement; the tinnitus generally persisting a brief period, in some instances a few days, after the suspension of this mode of treatment. A surprising improvement in hearing power was at the same time noticeable in many of these favorable cases. The range of audition was increased, and continued to improve for months, even after the treatment by sounds had been discontinued.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, February 3, 1887.

The President, Thomas M. Drysdale, M. D., in the chair.

Emmett's New Operation for Prolapse of the Posterior Vaginal Wall, or so-called Laceration of the Perineum.

Since I have become familiar with the subject, it has each day seemed more incomprehensible to me why the Emmett operation has not come into more general use. I have come to the conclusion that the fault lay in defective description of the operation as set forth in most cases, and in the fondness of men for working on the skin perineum, and not in the operation *per se*. The operation as described by most of the writers on the subject is hopelessly mixed up with long discourses on side issues. Too much is left to be understood from diagrams alone, with insufficient attention to details in the procedure. These are prominent faults in the descriptions given by Drs. Emmett and Dudley. Dr. Dudley also obscures his paper presented in *Pepper's System of Medicine* by introducing several "modifications." The first of these is one of the essential steps in the operation, though somewhat obscurely described by Dr. Emmet in the *third edition of his Gynecology*. It consists in carrying the denudation into the vaginal sulci. The second consists in passing deep sutures where Dr Emmett passes superficial ones. In reality Dr. Emmett's "superficial" stitches are only relatively superficial. His description of them distinctly calls for their being passed deeply enough to include the posterior wall. My excuse, therefore, for offering a contribution on such an old subject, is to attempt to make the steps of this operation clear; and if I seem tedious in detail to those who are familiar with the subject, I hope you will bear with me patiently.

The belief that the female perineum or perineal body gives any support to the pelvic viscera is an erroneous one. The distance between the uterus and the perineal body is quite measurable, and the intervening tissues, which consist merely of the mucous vaginal canal and surrounding connective tissue, are by no means of such a firm character as to be able to uphold the uterus, either *per se* or though the support given by the perineal body below. The only way this body could give the supposed support

would be by the uterus resting directly upon it. Dr. Emmett puts it very happily when he says, "it would be as rational to assume that a man's pantaloons were supported by the legs resting on the instep or foot." The principal support of the pelvic organs is their ligamentous attachments, on the same principle as the organs contained within the abdominal and thoracic cavities are suspended. A good proof of this is the fact that we constantly see women going about their daily work who have their superficial or skin perineums, not including the fascius or muscles, torn even to the sphincter ani, and who never have suffered any inconvenience therefrom, and who probably never will. The cause of all the various ailments following parturition, beginning procidentias, etc., will be found inside the vagina on the posterior wall, If any one will place his fingers on the posterior vaginal wall of a woman who has never borne a child, and move them first to one side and then to the other, he will find a firm resistance to pressure in any direction. If he now introduce his finger into the vagina of a woman who has had an injury to the pelvic floor during parturition, he will fail to meet with the resistance which he met in the first case. He will find instead a *rectocele* of greater or less extent, with deep diverging sulci running up each side of the recto-vaginocele, into which he can easily sink his finger without finding much resistance, and yet the external or skin perineum may be perfect. To fully and clearly understand this change, it will be necessary to consider the attachments of the pelvic viscera. The pelvic fascia descends until it reaches its attachment on a line drawn from the symphysis pubis to the spine of the ischium, where it divides into two layers, the outer or obturator and the inner or recto-vesical fascia. This line of separation in great part also corresponds to the line of attachment of the levator ani and coccygeus muscles. The levator ani extends from this attachment downward, and passing under the vagina is inserted into the rectum at different points. It is covered on its upper surface by a reflexion of the recto-vesical fascia, which binds it closely to the vagina and sphincter vaginæ muscle, and on its under surface by a reflexion of the obturator fascia, which binds it closely below. The transversus perinei, when it exists at all, arises from the pubic arch, and its fibres are lost in the sphincter vaginæ directly under the vagina. In speaking of the use of the sphincter vaginæ, Dr. Goodell says that "the property of this muscle is to pull down the rigid clitoris into contact with the male organ, to squeeze out the contents of the vulvo-vaginal glands, and to compress the dorsal vein as well as the bulbs of the vagina, so as to obstruct mechanically the current of blood, and produce a turgescence of these erectile organs." If this be correct, we have an explanation of the loss of sexual pleasure and desire so often seen in women who have suffered from a tear of this muscle. The recto-vesical fascia sends out reflexions from its bony attachments also over the vagina as well as over the other pelvic contents, forming the strong ligaments which hold them in place and give firm support to the different venous plexuses; amongst others the vaginal plexus.

The advancing head of the child, under certain circumstances, crowds the soft parts in advance as it sweeps along the pelvic floor and the fascius and muscles just described, becoming over distended, separate and retract, forming deep sulci laterally. Frequently the injury is sub-mucous. The external soft parts or skin perineum may be torn or not; very often it remains perfectly intact. There is no question in my mind that this injury is caused with unnecessary frequency both by the injudicious use of the forceps and by our vain efforts to "support the perineum." As a rule, our patients would be far better off if we were to throw our forceps away and keep our hands off the perineum, as far as any idea of giving it support is concerned. If we hold the head back, the vis-a-tergo must be spent somewhere, and that somewhere is the pelvic floor which suffers accordingly. The mere rupture of the fascius and muscles would cause the woman little trouble of themselves, but the results are far reaching. The fascius being the chief support of the blood-vessels, we now have these large veins with no support but their own walls; consequently we soon have a chronic engorgement, with dilatation and a very sluggish return of blood from the parts. The viscera become engorged and heavy. The anterior wall, which has lost its main support, the posterior wall, begins to roll down and out, forming a cysto-vaginocele; the posterior wall gradually pushes forwards and bulges from the vaginal orifice as a recto-vaginocyle. The fundus uteri becomes or remains enlarged, and falls backward from its weight and the traction of the vaginal wall. Gradually but surely the ligamentous attachments of the uterus are stretched, and the whole organ slowly descends, dragging everything with it. We eventually have all the phenomena of com-

plete procidentia if things go on unheeded. This theory of the injury in the female pelvis in parturition is by no means new. It is substantially the same view held by Emmett and expressed by Hadra in the *Amer. Jour. Obst.*, April, 1884, by Wylie in the *N. Y. Med. Rec.*, March, 1885, Skeene in the *N. Y. Med. Jour.*, April, 1885, and by Jas. Price in a paper read before the Philadelphia County Medical Society last spring.

The old operations, devised on the supposition that the injury of the perineal body was the cause of all the symptoms, included far more labial tissue than had been involved in the tear, and were entirely inefficient for restoring the pelvic floor. They caused an unnecessary barrier to coition, and frequently left the patient with a certainty of return of all her ailments, and a probability of the tear being reproduced at a subsequent labor. The only satisfactory surgical procedure suggested as a cure of the injury is that of Dr. Emmett, of New York, for "restoration of the pelvic diaphragm." The patient is placed in the dorsal position and the labia separated by assistants; hook a tenaculum or a ligature (which remains a permanent landmark to the end of the operation) into the crest of the rectocele and draw it upwards, without undue traction, to near the meatus, and place it in the hand of an assistant; hook another tenaculum into the labial tissue on each side directly opposite to or in the lower caruncle or remains of the hymen. If slight traction in diverging directions be made on all the tenacula at the same time, three triangles are formed, having the crest of the rectocele for their common apex. The base of the first is a line drawn from caruncle to caruncle, and the bases of the others a line drawn from each caruncle to a point far up the sulcus of the same side. On denuding these surfaces, and bringing the three tenacula together "the vaginal canal will be found reduced in size, the perineum will have been apparently drawn up towards the arch of the pubes, and the tissues of the previously gaping outlet will have been rolled in until the vaginal entrance is no longer larger than that of any female who has not given birth to a child at full term." The posterior wall is brought firmly up against the anterior wall and bladder, giving them their natural and necessary support and preventing their rolling down and out. Care must be taken not to denude too much surface in the sulci, as failure may result, the sutures cutting out from undue traction. The scissors should be used for all plastic work in the vagina. Any one becoming accustomed to their use will never go back to the knife. The bleeding is infinitely less, and much time is saved by the celerity with which they can be handled.

The most essential part of the operation is the introduction of the sutures. They are passed from the apex of each sulcus toward the operator. A tenaculum is hooked into the apex of one of the sulci and drawn away toward the cervix uteri, thus preserving the line on which the sutures are to be introduced. The sutures are then all passed toward the operator to the bottom and median line of the sulcus, plenty of tissue being included; the sutures emerge at the median line of the sulcus and are reintroduced in the same spots and carried away from the operator, emerging just beyond the freshened edge of the rectocele directly opposite the original point of introduction on the other side of the sulcus, thus taking a **V**-shaped course. The number of sutures is usually four or more. The other side is sutured in the same manner. When these sutures are all drawn up into place and closed, there remains a small triangular space of freshened surface in front of the rectocele, which is closed by the so-called crown-stitch and one or two superficial external stitches. The crown-stitch is introduced through labial tissue at the lower caruncle, the original point of introduction of one of the tenacula, carried across through the crest of the rectocele and then through labial tissue at the lower caruncle on the opposite side. All the other sutures are now lost to view within the vagina. The resulting shallow line directly in the median line of the perineum is closed by one or more superficial external stitches. They are passed deep enough to include a portion of the posterior vaginal wall.

The day for plunging a great perineal needle through gluteal tissues, skin, muscles, fascius, nerves, and blood-vessels, is past. It is as much a relic of barbarism as searing the stump of an amputation to stop hemorrhage, and causes much pain and suffering. The material of the suture is immaterial. Catgut can be either shotted or tied. As moisture causes the gut to swell, it should be shotted as soon as passed and fastened to the pubic hair with a pair of hemostatic forceps. This will keep them out of the way of the operator. Dr. Emmett always uses silver wire twisted and then shotted, so as to be easily found; the end is bent over and lies flat on the tissues. Silk-worm gut should always be shotted. It makes an excellent suture, and forms a good splint to the tissues. Whatever is used, the stitches are

equally hard to find and remove. A very easy method for either wire or gut is the use of "Aveling's wire coil." These can be made by wrapping a piece of silver several turns around a straight needle or other small staff to form a close coil about half an inch in length. This coil is slipped over the two ends of the suture and secured in its proper place by a compressed shot. In removing, snip off the shot, remove the coil, and the suture has ends as long as the coil was. The after-treatment is very simple. If the patient would stay quietly in bed, she would recover with perfect union without the doctor's attention. As a rule, the patient complains of no pain, and opium and alcohol are not needed. The bowels are kept soluble from the first, and the urine is passed every four or five hours, the patient getting on her hands and knees if necessary. There is no necessity for binding the knees together, nor for keeping the woman in one position for days. The stitches may be taken out in eight days.

Dr. M. Price described a plan for the temporary securing of sutures at the moment of insertion. The ends being left long, two perforated shot are slipped on: the first one is to be the permanent fastening, and is left loose; the second is compressed to secure the suture ends together and to prevent the other from stripping off until the time for final closing, when the first is pushed down and compressed.

Dr. Joseph Price described several ways of securing sutures so as to avoid imbedding the free ends of silver ones, and to secure easy extraction. Over the silver wire pass the Aveling coil and shot; this will greatly facilitate its removal. He also made some critical remarks on different methods of operating for perineal restoration. The inside method of Emmett gives the best results. The use of well-prepared catgut for the sulci sutures materially facilitates the operation. Set the sutures fresh from the alcohol, and drop a shot over before they swell.

Dr. Chas. Meigs Wilson stated that the difficulty of representing the operation diagrammatically is owing to the fact that the plane of the posterior wall of the vagina is altered by the traction upon the tenaculum holding the crest of the rectocele. The needle figured upon the blackboard by Dr. Packard was not a Baker Brown needle, as stated by Dr. Packard, but a modified staphylorraphy needle—the needle arm being longer, thinner, and having a greater arc of curvature than the ordinary staphylorraphy needle. It was first devised by Dr. E. Wilson to use in uniting the freshened surfaces in Emmett's operation upon the cervix. The objection to its use in colporraphy operations is that owing to the shortness of the needle-arm, the shoulder of the needle, *i. e.*, the junction of the needle-arm with the handle, made such a large opening in the mucous membrane of the vagina that the stitch was liable to tear out, especially if there was much tension before union had taken place.

Dr. Longaker spoke of the advisability of the primary operation. He believes all forceps with long blades and large heels will do damage to the vaginal outlet. He has seen transverse tears of the outlet after natural as well as instrumental labor. It has been remarked that perineal ruptures may exist without causing any symptoms, but this is no reason why tears in general should not be repaired. He believes in performing the primary operation in every case. He likes the Chinese silk for sutures. He has examined a perineum immediately after labor and found it apparently intact, and a month later found a rectocele and cystocele, indicating a submucous tear.

Dr. Joseph Price, upon request of the President, remarked that he had seen Mr. Tait operate for a complete tear into the rectum, also for partial laceration and rectocele. He operates so rapidly that it is difficult to follow him. He makes two scissors cuts one on each side of the laceration, splitting the tissues from the centre line laterally and forward. He removes no tissue, but throws one flap inside and the other out, and closes by interrupted buried sutures of silk-worm gut. In the complete rent, he splits the septum laterally, turning one flap into the bowel, the other into the vagina, and closes by interrupted transverse buried sutures, with two or more external sutures.

Dr. H. A. Kelley stated that this was not original with Mr. Tait. It had been originally devised by A. R. Simpson, of Edinburgh, and a description, with illustration, is to be found in Hart & Barbour's Manual.

Dr. Baldy, in closing the discussion, stated that the needle used by Dr. Emmett was round, slightly curved at the point, and from three-fourths to one inch in length. He uses it with a needle-holder, and as a rule prefers to have it threaded with a silk loop, into which the wire sutures are hooked.

Dr. Baldy has now in his care a patient whose fourchette is perfect, but scar-tissue can be felt inside of the perineum, and there is some little prolapse of the posterior wall. When she was delivered some weeks ago, the

need of an operation became apparent, as at that time the anterior wall and bladder prolapsed before the head, in a mass as large as a base ball. He does not sympathize with the total condemnation of the forceps; they are needed sometimes, though frequently abused; neither does he approve of the so-called support of the perineum, either by towel or by hand, nor the idea of holding the head back, because these methods deflect the force of the uterine contractions against the posterior vaginal wall and the pelvic floor. He has seen cases which had been operated on by the old method by eminent gynecologists, in which the result was a perfect external perineum, but in which the pelvic floor was as badly off as it had been before the operation. The floor was completely restored by the Emmett method subsequently.

Dr. Jos. Price read an extract from a private letter from Dr. Emmett to himself: "I am very glad that the woman who was operated on has fallen into your hands, so that you may be able to make a report of the exact condition after labor. I have not kept any accurate account, but I think I have heard of some twenty cases who have gone through labor without accident after the operation at the vaginal outlet had been done. On the other hand, I have not heard of a single case where the parts were torn after the operation, which is of more value, for I should be more likely to hear promptly of the failure than of the success."

Placenta Prævia.

Dr. Jos. V. Kelly reported the following case: K. W., fifth pregnancy, had a vaginal hemorrhage, December 28, 1886. The bleeding was quite profuse, but ceased spontaneously. On examination, the os admitted with ease the index finger, which came directly in contact with the placenta. The patient was supposed to be nearing the completion of the eighth month of pregnancy. She was enjoined to rest in bed, and dilute sulphuric acid was administered. Several days later the hemorrhage recurred and again ceased spontaneously. She kept on dribbling a little each day until January 11, 1887, when she had a violent hemorrhage, and I determined on active interference. Her pulse was 120, she was very pale and had attacks of fainting. The os was dilated to the size of a half-dollar, and dilatable. I gave her fifteen drops of Squibb's fld. ext. ergot. There was no decided pain, though the patient said she felt some slight bearing down. I brought her to the edge of the bed, with her knees flexed, and found a decided thinning of the placenta toward the right sacro-iliac symphisis. It was difficult to rupture the membranes without detaching the placenta, so I made firm pressure over the fundus, which caused the head to descend, and I then ruptured the membranes against the vertex. The waters drained off. the uterus condensed, and the bleeding ceased. I then gave twenty drops more of the ergot, and slight pains were noticed shortly afterwards. I still kept my index and middle fingers in the rent I had made in the membranes and the edge of the placenta, endeavoring to prevent any bleeding by pressing the placenta against the left side of the os. The pains became stronger, and the head descended, and the bleeding again returned. I endeavored to accelerate the labor by encouraging the woman to bear down and by making strong pressure over the fundus, but as these measures did not produce the desired result as rapidly as I wished, and the head having passed the superior strait, I applied the forceps and delivered. There was no further hemorrhage, and the placenta was expressed by Crede's method in fifteen minutes. The woman received a vaginal injection of warm vinegar, as well for its antiseptic as for its hemostatic properties.

The fœtus was of fair size for the eighth month, and was nearly lifeless. Artificial respiration, mouth to mouth, revived it, and it lived thirty hours. The mother was in a very exhausted condition, and was given brandy and ammonia for nearly a week. The pulse after delivery was 140. She was also given plenty of milk and broth, and not allowed to raise her head off the pillow for a week. She has since entirely recovered. No tampon was used in this case. Ether was not administered.

Dr. M. Price had recently attended four cases of placenta prævia at full term; one of them, a very desperate case, had been tamponed. The cervix was dilated to the size of a half dollar. He was urged by his consultant to introduce his hand, turn, and deliver, which was, much to his surprise, accomplished in ten minutes, with child and mother both saved. The four children were all saved, and the mothers also, although one of the latter died from anæmic causes three months later. He would at once, when called to such a case at full term, or in premature ones, if he considered it advisable, dilate, turn, and deliver. The method adopted in these four cases is that now adopted by the best authorities. Tampon-

ing at term he considers dangerous, and involving a loss of valuable time, hazardous to both mother and child.

(*To be continued.*)

NEW YORK PATHOLOGICAL SOCIETY.

Stated meeting, February 23, 1887. T. Mitchell Prudden, M. D., President, in the chair.

Brain of a Suicide.

Dr. W. H. Porter presented the brain of a suicide by a pistol shot, the bullet having passed directly through on the line of the temples, dividing both middle cerebral arteries and breaking both orbital plates.

Surgical Kidney and Liver.

Dr. Porter presented the liver and kidneys of a woman who had died about a week after removal of an abdominal tumor, probably a hæmatocele. For the first five days after the operation she did well. The temperature then went up, the urine, which had before the operation been normal, rose in specific gravity, contained albumen and pus. The autopsy showed a little suppuration along the abdominal sutures; no peritonitis. The interesting lesions were in the liver and kidneys; the liver showed extensive parenchymatous and fatty degeneration, slight cirrhosis; the kidneys showed also parenchymatous metamorphosis, less in degree; the heart showed some granular degeneration. At the previous meeting of the Society, Dr. Porter had expressed the view, sustained by a number of autopsies, that many so called septic cases after surgical operation were really cases of death from failure of function of the kidneys brought about by the influence of the anæsthetic. The primary and most extensive change after the operation seemed to be in the liver, and the secondary one in the kidney; the heart was affected in a less degree still.

Tricuspid and Mitral Regurgitation.

Dr. Porter also presented the heart of a man in which were found marked tricuspid and mitral insufficiency; the right auricle was greatly dilated, while the right ventricle was quite small. The primary lesion seemed to have been on the right side. A mitral and tricuspid regurgitant murmur had been recognized during life. The man had had jugular pulsation, œdema, dyspnœa, rheumatism. There was perihepatitis and some spots of cirrhosis in the liver.

Gall-stones; Hemorrhage after Paracentesis.

Dr. Porter presented the liver and a large blood-clot, in a case of gall-stones in a woman thirty-two years of age. She had, for eight or ten years, at times suffered severe pain in the right side. Otherwise, she had been healthy. On entering the hospital she was jaundiced; the temperature ranged from 103° to 107°; there was tenderness over the abdomen. An hepatic abscess was suspected, and the needle of the aspirator was introduced, but with a negative result. Before the autopsy was made it was supposed there were gall-stones, and this proved to be the case, there having been counted in the gall-bladder and ducts as many as eighty-six. The gall-bladder and all the ducts were enlarged; the common duct was pervious, but it seemed probable a stone may at one time have oscillated back and forth in it, causing temporary obstruction. Squeezing the liver caused numerous little stones to appear at the divided ducts. Dr. Porter was inclined to think that the stones had formed in the gall-bladder, and had been backed up into the smaller ducts. The liver showed softened spots, apparently ready to break down, very extensive parenchymatous and granular change, and slight cirrhosis. An interesting feature in the case was the slight hemorrhage which had taken place along the entire course of the needle of the aspirator, and a large clot had formed in the peritoneum, between the liver and diaphragm.

There were also parenchymatous and granular changes in the kidneys, some fatty degeneration of the walls of the heart, endometritis and granular condition of the cervix, and cystic degeneration of both ovaries.

Hip-joint Disease.

Dr. L. H. Sayre presented the head of the femur and some pieces from the acetabulum, removed in a case of disease of the acetabulum and head and neck of the femur, in a boy thirteen years old, who had always walked, his sister said, as if on a wooden leg, and who six weeks ago began to have chills and fever, loss of appetite, and pain in the hip. The gluteal region was large, and later deep-seated fluctuation was discovered, which was cut down upon and four ounces of pus were evacuated. Proceeding farther, it was found that notwithstanding the absence of crepitation and of some detritus in the pus, there was complete degeneration of the cartilage in the joint, necrosis of the acetabulum, and perforation of the head of the femur, with considerable necrosis of the neck. Excision was performed, and the patient was then doing well.

Abscess of the Lung.

Dr. L. E. Holt presented the lung of a child three weeks old, in which there was an abscess in the lower lobe on the right side, containing four or five ounces of pus. The curious feature in the case was the absence of severe symptoms until two or three days before death. At first the symptoms had been rather those of a broncho-pneumonia, then flatness being present, aspiration was done, drawing out on one occasion three ounces of pus, and on another about one ounce. The diagnosis was then made of empyema. At its last illness the house physician had inserted the needle twice, and failed to find fluid. The tissue surrounding the abscess and between it and the pleura seemed to be dense fibrous tissue. The specimen was referred to the committee on microscopy. There was no fluid in the pleural cavity. The right lung, with its abscess, took up nearly the entire space in the chest cavity.

Stricture of the Œsophagus.

Dr. Frank Ferguson presented the œsophagus of a child aged two years, which three months before had swallowed a small quantity of caustic potash, since which it had not retained any food. The stricture at autopsy was found about midway the œsophagus, and admitted a small probe.

Adjourned.

NEW YORK ACADEMY OF MEDICINE.

Stated meeting, February 17, 1887.

A. Jacobi, M. D., President, in the chair.

The President read an address in which he again referred to the absurd position in which physicians and the entire profession were being placed by reports of wonderful operations, or wonderful reports of operations, which appear from time to time in the daily press.

Dr. C. L. Dana read a paper entitled

Spastic Ataxia and the Combined Sclerosis of the Spinal Cord.

Out of an extensive amount of literature and a large number of cases relating to disease of the spinal cord, he had been able to find only sixteen cases in which autopsies had been made which he considered as belonging to the class of cases under consideration. In addition to these sixteen cases, he reported eight which had come under his own observation, in only one of which a post-mortem examination had been made, a case of Dr. Graeme M. Hammond. The usual post-mortem findings in these cases were a sclerosis or degeneration, mostly in the three long system-tracts in the cord, that is, in the direct cerebellar tracts, the pyramidal tracts, and the column of Goll. The disease, however, sometimes extended laterally, invading even the cells of the cornua. It was usually most marked in the upper dorsal region. The term combined fascicular sclerosis might be employed to designate the condition if it were not for the fact that this lesion was sometimes present when the symptoms during life had been those of ataxia with flaccid paralysis and not spasm. Also, in the cases typical clinically the lesion was not always strictly fascicular. The term used by Gowers, ataxic paraplegia, was objectionable.

Two of Dr. Dana's cases were females, six were males. The facts drawn from his cases and the sixteen others in which an autopsy had been made were the following: Syphilis was rarely present; a neurotic family history was common; in cases occurring in early life there was usually a history of sexual or alcoholic excess; in later life the history was one of physical strain and exposure. It began usually with ataxia, then stiffness in the legs and trembling; sexual power declined early; there was temporary bladder difficulty; a feeling of numbness, and pains of fulminating character occurred, but did not last long. Anæsthesia in spots often disappeared readily under treatment. The muscle sense was often good. There were no gastric nor enteric crises. The spastic symptoms were usually in the lower extremities, but sometimes involved the upper extremities.

In treatment, the nervous state might call for bromides; if there was a history of syphilis, anti-syphilitic treatment should be thoroughly tried; absolute rest was very important; slight sensory symptoms often disappeared readily under the use of electricity.

The prognosis as to length of life was better, he thought, than in typical cases.

Drs. Starr, Brill, and Birdsall, in discussing the paper, thought that clinically a class more or less like that described by Dr. Dana might be formed from a large number of cases, yet they were doubtful whether they constituted a distinct type of disease. The distribution of the pathological lesion was irregular, and the symptoms varied accordingly. They agreed with the author as to the difficulty of giving an appropriate name. Dr. Seguin related a case of spastic paraplegia, and said the post-mortem findings were those of sclerosis in the posterior and lateral

columns, and the microscope showed that the lesion also extended to the extreme lateral portions of the spinal cord, and it was rather irregular at different levels. The President suggested that the peculiarly irregular distribution of the disease might be accounted for by its following the course of the fine blood vessels rather than of nerve fibres.

Periscope.

Ocular Symptoms in Acute Cerebral Disease.

At a late meeting of the Ophthalmological Society of London, Mr. G. A. Berry read three cases of acute cerebral disease with ocular symptoms. His first case was one of acute ophthalmoplegia externa in a little girl, aged two years and a half. There was a history of gastro-enteric catarrh five months before admission. The present illness began three weeks ago with cough and headache. Ten days before, something wrong was noticed with the sight. There was almost complete ptosis of both eyes, with absolute divergence of eyeballs—in fact, a condition of almost complete ophthalmoplegia externa. The child was mentally very apathetic; once she had a very severe screaming fit; the knee-jerks were absent. After treatment by iodide of potassium for two weeks, distinct improvement in the general condition began, and the ophthalmoplegia was less marked. There was a scrofulous condition of one finger. The pathology of ophthalmoplegia was reviewed. Perhaps the condition was dependent on tubercular disease about the ocular nuclei. The second case was one of megrim associated with spasm of convergence, in a girl aged eighteen. The possibility of hysteria being the cause was considered. On one occasion the patient had an attack of apparently insurmountable conjugate deviation of the eyes to the left. Extraordinary abnormalities of temperature of the body were observed. The corpora quadrigemina or the cortex might be the seat of the nervous lesion. The third case was one of recurrent attacks of bitemporal hemianopia. The patient was a man aged fifty-three, who had suffered from headache and drowsiness. Both temporal halves of the fields of vision were extremely defective up to about 5° from the points of fixation. On six occasions, at intervals of about one week and for three or four days, vision became affected and the temporal fields of vision dimmed or obliterated, whilst at the same time the heart's action was markedly slower than during the periods of intermission of the ocular symptoms. Pressure on the chiasma in an antero-posterior direction might be the cause of the hemianopia.

Dr. Gowers said the cases were difficult. He agreed with Dr. Berry that it was highly probable that different cases of external ophthalmoplegia had different pathological lesions, especially judging from what was known of ophthalmoplegia interna. The loss of light-reflex, usually attributed to degeneration, might pass away even in tabes. Where recovery took place, the lesion could not be a destructive one, though there might be some nutritional change. With regard to the first case, he doubted whether it could be due to distension of the aqueduct or to a simple tubercular lesion. Distension of the aqueduct was frequently met with without paralysis of ocular muscles. Sudden lesions were generally vascular. Thrombosis was common in children; in this case it was probable that a thrombus had occurred in the artery leading to the ocular centre. In the second case, he agreed that the case was not one of hysteria. Divergent strabismus was conclusive against hysteria. As to the third case, no doubt internal hydrocephalus was an occasional cause of pressure on the chiasma, and blindness. He referred to a case where first the decussating and afterwards the non-decussating fibres were affected by the distension of the third ventricle.

Case of Cocaine Poisoning.

Dr. C. S. Kilham thus writes in the *Lancet:*

On November 9, 1886, at 12:10 noon, John B., accidentally took four and four-fifths grains of cocaine hydrochlorate in the form of solution. At 12:30 he was seized with severe cramps in the stomach, nausea, throbbing and feeling of bursting in his head, failure of eyesight, loss of use of his legs, incoherence of speech and confusion of ideas, and drowsiness, but could always answer questions if roused. No delirium; appeared as if drunk, and not quite helpless. Brandy was given, and he vomited after it,

but only the remains of food. About 12:50 he commenced sweating most profusely, shirt, etc., being soaked through, perspiration streaming down his face and body, and his head steaming. Pupils were normal and equal. No loss of taste. The sweating lasted some time, and was succeeded by very severe prostration, shivering, and feeling of impending death. At intervals the patient had severe cramps in the stomach, with retching and vomiting of a quantity of clear mucus, which relieved the pain. About 1:15 p. m. the pulse became intermittent, missing every fifth beat. This was accompanied by cyanosis of the face, and intense feeling of suffocation over the cardiac region. Relief was afforded by sinapisms. The pulse varied from 80 to 86, never more, and became gradually regular. About 1:45 p. m. he began to have cramps in the legs and feet (especially on dorsal surface of right foot), and tingling and numbness in both hands. Later on the pupils became dilated. The vomiting and cramps ceased about 4 p. m. (unless food was taken), but the drowsiness, throbbing of head, and prostration continued up to 6 p. m., when the patient began to get warm and feel relieved. The improvement continued, and he could be moved at 8:30 p. m. There was great weakness, with swimming of head all night.

Next day there was still weakness, continual vomiting, a dry, leathery feeling in the mouth, with loss of taste, partial loss of power in the legs, and tingling and numbness of the fingers, especially of the right hand. These symptoms commenced nearly thirty-six hours after taking the cocaine, and most of them disappeared in twenty-four hours. The loss of power in the legs lasted three days, and the tingling and numbness of fingers longer. He was not able to write a letter until the sixth day, as he could not feel the pen between his fingers before. An emetic was first given, with sinapisms over the heart and stomach ; afterwards warmth and stimulants (principally compound spirit of ammonia).

Remarks.—The solution of cocaine had been made at least twelve months, but appeared all right. The patient was in the habit of taking ¼ gr. of cocaine for neuralgia of the stomach. The dose taken was 4⅘ gr. of hydrochlorate of cocaine. The officinal dose is up to 1 gr. Martindale, in his book on " Coca, Cocaine, etc.," mentions two cases where larger doses were taken. In one case (of attempted suicide) 23 grs. of cocaine were taken without " seriously injurious effect." In the other case 32 grs. of cocaine were taken within three hours, but the symptoms varied considerably from those in the case under notice. The most remarkable symptoms were the severe sweating, the intense prostration, and the intermittent pulse. The last symptom I have not seen mentioned before.

Treatment of Chronic Constipation in Childhood, and its Sequel, Atony and Dilatation of the Colon.

After discussing this question in the *Lancet* (December 11), Dr. W. B. Cheadle thus concludes:

" My object in these lectures is not so much to describe the cause and symptoms of constipation as to point out the disastrous results of mistaken treatment, and to enforce the necessity of a more rational procedure. Look at the evil effect of strong purgations —how they enervate and wear out the tone of the bowel. No occasional purge of rhubarb or scammony is efficient to cure. Look, again, at the evil effect of frequent enemata. Enemata are only to be used on an emergency. They, equally with strong purges, impair tone and do direct harm by actual dilatation. In confirmed cases of constipated habit, treatment must not be intermittent, but continuous; the daily administration of appropriate remedies steadily, for a considerable period, is absolutely essential. Intermittent treatment is abortive, ineffectual, and aggravates the evil. What, then, is the proper treatment for these cases? First, be sure that there is no malformation, no intussusception, no sore about the anus, rendering defecation painful. Then use saline laxatives. Their mode of action is by increasing the flow of secretion rather than by stimulating peristalsis. Thus tone returns when distension is relieved by the easy evacuation of fluid stools. Further aids to this are strychnia, nux vomica, iron, and belladonna. They act by increasing the muscular tone and nutrition, not by stimulating peristalsis directly. In the case of little children up to two years old simple carbonate of magnesia in milk is sufficient (5 to 10 or 20 gr.); this is better than the piece of soap in the rectum, or the repeated castor oil or manna so constantly advised. In older children, the sulphates of magnesia and soda, with the tonics named above, and daily massage with castor oil or cod-liver oil, are most useful. In older children still, a pill of aloes or euonymin, with sulphate of iron and nux vomica, may be given as an alternative to the salts and strychnia, but no frequent rhubarb, or scammony, or podophyllin, or jalap

(these are for the relief of temporary difficulty only); in mild cases, perhaps, or if the liver is not acting, a dose of calomel, grey powder, and soda, or senna. Regimen is an important element in the treatment if the child should have chronic constipation: abundant water, pure, not hard; 'salutaris water' is excellent. In little children add a good infants' food to milk; fruits; fruit jellies; treacle; cooked green vegetables of the softer and more delicate kinds. Some variety in food is useful; a good mixture is better than a monotonous diet. It is, I think, extremely doubtful if coarse food is useful in the long run. It causes atony and weariness of muscle eventually by over-stimulation. And you must insist on regular evacuations. Take care that the stools are not dry and hard, or the child will resist action and increase constipation. Other useful adjuncts are—abundance of fresh air, which aids in improving nutrition; and exercise, which mechanically aids the passage of the contents of the intestine down the tube, and improves general health and muscular tone."

A Remarkable Midwifery Case: Extraordinary Thickness and Induration of the Os Uteri.

"I think the following case is worth recording," says Dr. Wm. Wigmore, in the *Lancet:*

"At 3 a. m. on December 8 I was called to Mrs. H——, aged thirty-nine, in labor with her third child, the last being two years old; pains had been going on since the afternoon of the day before. On examination, I found the os dilated to about the size of a five-shilling piece, head presenting; anteriorly, the os was thickened and swollen into a mass under the pubes, the rest being quite an inch thick and tough. The liquor amnii had escaped a short time before. I tried for some time to dilate, but finding I could make no impression, and the pains getting stronger and almost incessant, I applied the long forceps, hoping that with the aid of them and the fingers I might be able to dilate; but directly I used any traction, the os came quite outside the vulva, and I found it useless to attempt it. If I had used more force I should have pulled child and uterus away together. The pains were still incessant, the patient calling out for something to be done. I saw there was nothing left but to divide the os. Before doing so I wished for another opinion, and sent for Dr. Griffith, of Harrow Road. He asked me to remove the forceps and let him try to dilate; but, like myself, he found it perfectly useless, and agreed with me that nothing but division would give her a chance of being delivered. I accordingly reapplied the forceps, and, pulling the os outside the vulva, proceeded to divide it posteriorly. The procedure was like cutting cartilage or tendon, and there was no bleeding; directly it was divided the uterus split right up over the head of the child, which was immediately expelled. The child was dead. I was now fearful of the consequences, daily expecting to find symptoms of metritis, cellulitis, or peritonitis; but, on the contrary, the temperature never rose above 101°. She never had any abdominal tenderness, nor even a fetid discharge, and is now quite convalescent.

"*Remarks.*—After the birth of her first child, the patient suffered from a fall of the womb, and after that of the second it became worse, and eventually quite prolapsed. She never sought any advice for it. During the whole of her present pregnancy she was sitting on it, which gave her much pain, and her favorite seat was a cane-chair with a hole in it. I suppose by the continual exposure and friction its character was quite altered. Having had a very large midwifery experience, and never meeting with a similar case, I am anxious to know what else I could have done. Craniotomy would have been of no avail, and I do not think that dismemberment would have been successful. I should also like to know how the peritoneum escaped—whether the recto-vaginal and vesico-vaginal folds were stretched by the gradual rise of the fundus and being held down below. I may here mention that after the birth of the child the uterus contracted well, the placenta came away without difficulty or hemorrhage, and the os was drawn well into the vagina."

The Treatment of Typhoid.

Professor Grancher, following in the steps of Professor Bouchard, gives the following directions for the treatment of enterica: Four principal indications result from the pathogeny of the disease—general antisepsis, intestinal antisepsis, antipyretics, and nourishment. As soon as the disease is suspected, M. Bouchard commences by the administration of a purgative which is renewed every three days. For the first four days, calomel is given in doses of one-third of a grain every hour as a general antiseptic. Intestinal antisepsis is secured by the administration of vegetable charcoal in powder (100 grammes), iodoform (1 gramme), and naphthaline (5 grammes). This is mixed with 50

grammes of peptone and 200 grammes of glycerine, which constitute the basis of the alimentation, and the black magma so formed is taken by tablespoonfuls every two hours. The bowels are washed out night and morning with carbolic acid and water (1 in 1000), each enema measuring one pint. From the beginning of the disease the patient takes eight baths a day until recovery, but instead of using water at a much lower temperature than that of the body, the difference is only of two degrees Centigrade, 38°, for instance, if the temperature is 40°. The bath is then cooled by a tenth of a degree per minute to 30°, but never below, so avoiding all shock and spasm. When the temperature remains high notwithstanding the baths, quinine is recommended, 30 grains being given in four doses in the course of two hours, and repeated after an interval of three days. Besides the glycerine and peptone associated with the antiseptics, the only other food allowed is bouillon, boiled with barley, and as a drink, lemonade with a little wine. Should complications occur, they should also meet with a vigorous reception. Extreme or prolonged delirium is to be treated by opium, and peritonitic symptoms by ice or mercurial ointment. Of 266 patients so treated by M. Bouchard, 31 died, giving a mortality of 11.7 per cent. The average duration of the disease was nineteen days, and relapses took place on the whole number in 20 per cent., and during the latter period in 10 per cent. of the cases. These figures speak for themselves, and there is one point about M. Bouchard's method beyond contestation. It is certainly thorough. But if, as it would seem, the patient spends thirteen hours in the bath and undergoes fifty or sixty other visitations of different kinds in the course of the twenty-four hours, it is difficult to see what time remains for repose.

Post-mortem Irritability of Muscle.

Dr. John H. Spitzly thus writes to the *Lancet:*

A young Hindoo, aged twenty, was admitted into our wards on February 28, 1886, and died on October 31 of phthisis pulmonalis. He was a remarkably thin and weakly-looking individual; but although he had a decidedly phthisical aspect, and suffered from cough, general emaciation, and diarrhœa, no dullness was perceptible on percussion of the chest-walls. The post-mortem examination revealed a large vomica with infiltrated edges, situated at the root of the left lung, which sufficiently accounted for our inability in detecting any marked alteration on percussion. Numerous small abscesses were also found throughout the substance of the left lung. The intestinal walls were of a dull clay color. A most peculiar phenomenon in connection with the voluntary muscles, however, more especially attracted our attention. About two hours after death had taken place, one of our students, who was inspecting the body, percussed the pectoral region, and, to his great astonishment, noticed that the muscles responded most energetically to the stimulus conveyed by the percussing finger, and contracted very promptly. On examining the muscles, I was able to produce most vigorous contractions of the biceps and flexor muscles of the arms, the pectorals, the sterno-cleidomastoids, the masseters and temporals, and also of the rectus femoris and other muscles of the lower extremity. The biceps and pectorals, especially, responded very promptly, and the contracting muscular fibres of the biceps in some instances rose to certainly half an inch above the level of the quiescent portion. The muscular substance itself was very soft and doughy to the feel, and of a pink color. Although I have very frequently seen a stimulus call forth fibrillary muscular contractions in emaciated persons suffering from phthisis, I have never before observed the same phenomenon in such a remarkable degree of intensity on the body of a person in whom life had already been extinct for two hours, and I should be much interested to know if this post-mortem phenomenon is common in cases in which the patient has very gradually succumbed to a chronic exhausting disease. Perhaps I should also add that the temperature at the time these observations were made was 90° F., and that the time of the year was what is here called the "dry season."

Epilepsy after Gunshot-Wound.

In the *Brit. Med. Jour.*, Dr. Hadden relates the case of a man, aged thirty-two, who was under Mr. Croft's care at St. Thomas's Hospital. There was no family history of epilepsy. In 1872 he was wounded in the left calf, and several shots were extracted. In six or seven weeks the wound was quite healed. Four months after the injury he began to have fits. For nine months they were occasional, but afterwards he had as many as twelve daily. The sciatic nerve was then stretched, and the fits ceased for thirteen years. They recommenced seven weeks before admission into St. Thomas's, when he fell to the ground from a ladder,

unconscious. During the week preceding admission, he had eight or ten daily. The fits began with a sharp twitching pain in the scar in the left calf; then there was a creeping, heating sensation passing up the leg and left side of the body to the head. The left side then became convulsed. The pupils were immobile, and the conjunctivæ insensitive. Finally, there were some general convulsive movements, and then rapid return to consciousness. The tongue was not bitten, nor were the evacuations passed. The scar was somewhat tender, and when pressed, he would at times have the sensation passing up the body, and sometimes a convulsion. Occasionally in the seizures he would roll about in bed, and sometimes there was opisthotonos. An attempt was made to stretch the sciatic nerve by extreme flexion of the hip, but the result was a violent convulsion. A few days later the nerve was exposed and freely stretched. The fits stopped for nine days. He then had occasional seizures, sometimes one a day, sometimes one every other day. Two occurred whilst the splint was being bandaged to the leg, and one during removal of the splint. The man wrote four months later to say that he had had no convulsion since he left the hospital, but he suffered from severe paroxysmal pain in the left calf, followed by the "fitty" sensations. There was no doubt that the attacks were genuine, the condition of the pupils and conjunctivæ and other points proving this. The interest of the case had reference to Brown-Séquard's and Victor Horsley's experiments on guinea-pigs. Epilepsy was induced by these observers after injury to the sciatic nerve. There was usually a latent period of from two to six weeks. In the man the incubation was four months. Opisthotonos occurred in the patient, as in the case of guinea-pigs.

Effects of Renal Calculi.

Before the Clinical Society of London lately, Mr. Howard Marsh read a case in which very severe symptoms were due to two small stones in an atrophied and movable kidney; failure to detect the organ by an anterior lumbar incision; discovery by laparotomy; successful removal of the kidney. The patient, aged twenty-five, unmarried, was admitted into St. Bartholomew's Hospital on June 29, 1886, with well-marked symptoms of stone in the left kidney, constant pain, severe exacerbations, frequent micturition, and pus and blood in the urine. As no improvement followed rest and medical treatment, it was determined to explore the kidney. For this purpose an incision, suggested by Mr. Willett, and which had several times been found highly advantageous for the removal of large kidneys, situated exactly half-way between the spine and the middle line in front, and vertical in direction, was made through the abdominal wall and fascia transversalis. The kidney, however, could nowhere be found, though a wide search was made. On a subsequent occasion the abdomen was opened in the middle line, and the hand passed in. The kidney was now easily detected, but found to be movable and atrophied. No stone, however, could be felt. The kidney was then removed by the ordinary lumbar incision. The patient made a bad recovery. On opening the kidney after removal two small stones were found in one of the calices. The author drew attention to the important fact that, though the symptoms were very urgent, the stones on which they depended were of very small size. He pointed out that, though the incision in the axillary line is ordinarily adopted for the removal of a large kidney, the posterior lumbar incision is preferable for the purpose either of mere exploration or the removal of a stone from the kidney; and he discussed the means that may be adopted for the detection and removal of small renal calculi. He also raised the question how far the symptoms in the present case may have been due to the fact that the kidney was freely movable.

Treatment of Typhoid Fever by Inhalation of Cold Air.

M. A. Sokoloff, of the Military Hospital of Krasnosesky, published some time ago interesting researches on a new method of treatment of typhoid fever. The author had remarked that the patients suffering from this disease who were placed in tents could without inconvenience respire air at a temperature of zero, and that coincidently the temperature of the body fell from 40° C. to normal. He was thus led to conjecture that inhalations of cold air might be employed with a therapeutic object in view. He experimented on twenty-three cases, and found that inhalation of air nearly at zero caused a more or less pronounced defervescence, though the action is, as might be expected, less lively than with cold-air or cold-water baths, and is at the same time more transitory. He found that the action varied under different conditions, the defervescence being least from midday to 6 p. m., and the greatest between the hours of 7 and 10 in the evening. The effects were less during

the first fortnight, the defervescence effected being less than 1° C., and lasting only for an hour and a half to two hours, whilst they were greater after the first fortnight, the defervescence amounting to more than 1° C., and lasting for several hours. The duration of the inhalation was found to be of little importance, a *séance* of ten minutes' duration being equal to one of twenty minutes. The best time was from twelve to fifteen minutes. The defervescence was not in direct ratio to the temperature of the air inspired, and air at very low temperature did not act any better than air at somewhat higher temperatures, because exposure to the former had to be curtailed. Depression or excitation of the patient diminished or suppressed the antipyretic action of the inhalations. The general effects of inhaling cold air were that the respiration was diminished in frequency by about four times in the minute, and became deeper; the pulse was lowered on the average six beats, and became more full. On the other hand, the skin and mucous membrane became less dry.

Value of Incision in Tonsillitis.

Mr. Charles Maclean writes in the *British Medical Journal:*

I am induced to remark on the above subject from the fact that I have found free incisions of more avail in quinsy than in any other kind of inflammation. It is a disease little amenable to ordinary methods of treatment. It is attended by an extraordinary, and in some constitutions, a very serious amount of suffering; and yet it is a local affection, and within easy reach. One book in my possession recommends opening the abscess when suffocation is imminent; another says that puncturing the swelling may be tried. The necessity of the former of these recommendations is at once obvious; but I would be inclined to anticipate this critical state, which occurs after prolonged fever and suffering. As to puncturing, I do not know that I have found it of any service at all. A large incision, however, seldom fails, in my experience, to modify the course of the disease almost at once. A case I had a little time ago serves to illustrate this. I was called in the evening to see a patient who was said to be speechless and to have "lock-jaw." His snowy-white tongue, his pulse and temperature indicated high inflammatory fever. I opened his mouth, cautiously inserted a bistoury, and made a good long incision in the most prominent part of the swelling. Free venous bleeding ensued for some minutes, and soon after it ceased the patient was asleep. In the morning, in reply to my question, he expressed himself as being "quite well." All the symptoms—constitutional and local—had vanished.

I have the greatest possible respect for the internal carotid artery, and no person can have a greater dislike for needless operations than I have. Here, however, there is a distinct object to be gained by operating, and, as regards the vessel in question, a vertical incision in the region of the tonsil cannot injure it, especially as in this complaint the swollen gland tends to push the artery outwards.

Cure of a Hepatic Hydatid by Puncture.

The following case is reported by Dr. F. A. A. Smith in the *Lancet:*

Mrs. K., aged forty-eight, struck her right side against the kitchen table about five months ago. She did not think anything about the accident, but soon afterwards felt a pain in the right side, which gradually enlarged, and extreme emaciation set in. Cancer was diagnosed by several medical men, and one thought the ribs were fractured. When I saw the patient, she was extremely weak and emaciated, and looked like a woman dying of cancer. On examination the ribs of the right side were found very prominent, with bulging of the intercostal spaces. Percussion dullness extended over the median line and downwards to nearly three inches below the ribs. The tumor felt firm and smooth, and gave one the impression of an enlarged liver. At a spot the size of a florin, an inch below the margin of the lower ribs, and two inches to the right of the median line slight fluctuation was felt. Diagnosing the case as one of either abscess or hydatid cyst, I plunged a No. 1 trocar and canula into the centre of the fluctuating spot, in a direction upwards and backwards, and drew off about six ounces of limpid, straw-colored fluid. A small piece of plaster was placed over the puncture, and a towel tied tightly round the abdomen. Nothing more was done, and the patient got rapidly well and is still alive. The only precautions I took were to stretch the skin so as to make the opening valvular and arrest the flow of liquid before the cyst was entirely emptied; thus no air was allowed to enter.

The interesting part of this case was the distinct history of a blow, and the rapid enlargement of the tumor and extreme emaciation. The fluid was examined carefully under the microscope, but no hooklets were detected.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

REMEDIES FOR ALCOHOLISM.

This was the important subject selected for a lecture by Prof. Alglave, of Paris, in a recent discourse at the Sorbonne. In our country, where prohibition is so much a question of the day, and where the supporters of teetotalism, high license, moderate drinking, and low license, are equally honest, it is interesting to learn the experience of competent observers in the Old World.

Professor Alglave fully recognizes the baneful effects of excessive indulgence. He describes the efforts to restrain it. There are temperance societies of various sorts; there have been female crusaders praying and singing in drinking places. Drinkers would leave—perhaps driven away by the dreadful singing—but to return the next day. It was also tried to render drinking more difficult by restrictive legislation, lessening the number of drinking places; but all these devices have failed. Attempts to enforce total abstinence result only in propagating secret drinking and stronger beverages. Restrictive legislation has been just as ineffective, as is proved from the official records kept in Holland and Switzerland, the only two countries in which complete data are obtainable. The records show that the districts having the fewer drinking places are just those presenting the larger number of alcoholism cases. Two shaded maps for each country, being projected side by side on the screen, demonstrated that alcoholism had increased almost precisely in proportion with the decrease in number of drinking places.

Then, what is the remedy? M. Alglave is of opinion that man will drink notwithstanding all that can be done to prevent him, and he is convinced that the only way to lessen the evil is to allow the sale of no liquor or drink contaminated with the slightest trace of amylic alcohol. Thus, if drunkenness is not prevented, at least alcoholism will be. To attain this result is not an easy task, still it is quite feasible. It is not sufficient to enact severe penalties against the sale of liquors containing amylic alcohol; such a course is even unjust to the retail dealer, who will pertinently say: "If you chemists, with all your science and laboratories, require half a pint of the liquid and several days to test it, how am I to judge of its quality?"

M. Alglave proposes a sort of mitigated State monopoly. The State shall supply dealers with chemically pure liquors at a stated price, allowing a fair profit, and deliver them in small bottles only that cannot be filled again. To prevent refilling, there

are several devices, one of which he favors, consisting of the affixing of a government stamp over the stopper, and the prohibition to have more than one or two bottles under way at a time. No dealer shall be obliged to purchase State liquor, but a pure article being easily procurable, severe penalties shall be inflicted for the sale of impure liquors. He will be punished, not for defrauding the revenue—that is only venial sin, in the eyes of many—but for poisoning the people. Another advantage of the system is that it would yield an immense revenue, permitting them to lower the taxes on many things. Switzerland has substantially adopted its provisions, the colony of Martinique and Venezuela are going to do the same, and other countries are making inquiries with a view to study the expediency of this plan.

We recommend it to the advocates of temperance in the United States.

OPINIONS OF AN ENGLISH PHYSICIAN.

It is interesting to learn the opinions of an eminent physician concerning things in general touching the profession, and a desultory talk of the kind from an observing man is well worth attention. In this way we may characterize a recent address by a busy practitioner of London, on his recent election to the presidency of the Clinical Society of that great metropolis.

He expressed the opinion that pathology and therapeutics now go hand in hand. Diagnosis was one of the most important elements of success in the career of medical men. A well-known barrister of his acquaintance, in his post-prandial chat, was wont to say that, to paraphrase an aphorism of Demosthenes, the first element of success at the bar was good animal spirits; the second, good animal spirits; and the third, good animal spirits. In the same way, he would be disposed to say that the great element of success in medicine was diagnosis. By diagnosis he meant careful and exact localization of lesions. It was not diagnosis to say that a patient had paraplegia unless the nature and site of the lesion was ascertained. As to the mere fact of some cases proving exceptional, he recalled the saying of Sir James Paget, that "an exception to one rule was in reality the first indication of another and possibly unknown rule," and might therefore be the means of enabling the careful and attentive observer to carry out useful observation on a new line.

The physician can and often does point to the arrest of phthisis in individuals and communities; the progress of Bright's disease might be staved off indefinitely if the patient only carried out the treatment laid down for him; but such cases scarcely admit of being shown, and in any case do not appeal to the attention in the same way as the more palpable results of the surgeon's intervention.

He deprecated anything in the nature of skepticism in regard to the use of drugs, and declared that when physicians used drugs they did so in good faith. Alluding to the class of drugs known as antipyretics, he said that, while they were useful in a certain category of cases, the mere knowledge that they lowered the temperature was not a sufficient justification for their use. It was necessary for the physician to know *how* the temperature was lowered before he ventured to lower it. The mere existence of fever was not a sufficient reason, and there were many cases in which it was doubtful whether a reduction in temperature was desirable or beneficial to the patient. The physician was not in a position to say that a high temperature was *per se* a symptom to be combated, since it might be a necessary item in the evolution of the morbid phenomena.

Referring to the employment of the salicylates in the treatment of acute rheumatism, he acknowledged that many of the inconveniences and sequelæ of that disease were abridged or prevented by its use. At the same time he enjoined a certain caution, especially in prolonged courses of the drug. He said that, since its use had become general, he had certainly seen deaths from rheumatic fever of a kind he had not met with before.

EXTRAORDINARY POWERS IN THE FEEBLE-MINDED.

It is a strange but well known fact that, in many persons who are idiotic or but little removed from the mental condition of idiots, certain powers of the mind may be developed to an extraordinary degree.

Remarkable precocity in the power of arithmetical calculations is frequently combined with a positive deficiency in other directions. In institutions devoted to the care of feeble-minded children such examples are nearly always present. Deficient in some faculties, others are developed to excess. Some such can carve and draw with great skill. Extraordinary memory is often met with, associated with very great defect of reasoning. One boy, in reading Gibbon's "Rise and Fall of the Roman Empire,"

skipped a line on the third page at his first perusal. Ever after, when reciting from memory the stately periods of Gibbon, he would, on coming to the third page, skip the line and retrace his steps, just as when he first re-committed the passage to memory.

Often the memory takes the form of remembering dates and past events. One boy never failed to tell correctly the name and address of every confectioner's shop he had visited in London, and could as readily tell the date of every visit. The faculty of number is usually slightly developed in feeble-minded children, while memory is fairly well developed; yet occasionally the power of mental arithmetic has been well developed. Improvisation is an occasional faculty. Memory of tune is a very common faculty among the feeble-minded; they readily acquire simple airs, and rarely forget them.

In none of the cases of idiot *savants* has there been any history of the possession of a similar faculty by the parents or sisters or brothers. In one case a necropsy is reported by Dr. J. L. Down, of London. The boy had a remarkable, indeed perfect, appreciation of past or passing time. There was no difference from an ordinary brain, with the exception that there were two well-marked and distinct soft commissures. Dr. Down's explanation of the phenomenon was that, as every movement of the house was absolutely punctual, he had data from which he could estimate the time by accurate appreciation of its flux.

Every form of mental deviation may be met with in the congenital feeble-minded. They may become the subjects of acute and chronic mania, of acute and chronic melancholia, and of dementia. Occasionally under the influence of acute mania, the feeble intellect of the youth becomes fanned into a brighter flame. The taciturn may become loquacious; the timid and respectful, proud and defiant; the amiable and tractable, abusive and destructive. Three remarkable instances occurred to Dr. Down of boys who had never been able to speak making use of well-formed sentences during the high febrile state of acute pneumonia or scarlatina.

It is of much interest to report all such cases, as they throw great light on the workings of the human mind in health.

—A Dubuque, prohibition Iowa undertaker, recently ordered stock from a Michigan coffin manufactory, and added this postscript to the order: "Put in one of the caskets a gallon of Old Crow whisky, and bill as embalming fluid."

Notes and Comments.

Horny Growth on the Penis.

Mr. Pearce Gould exhibited a specimen of harny growth on the penis to an English Medical Society. The patient was a man aged 50, who had had congenital phimosis. He first experienced difficulty in micturition about four years earlier, and was circumcised; the wound healed except in the middle line, where a small granulating surface remained; in connection with this surface two small warts developed; from the earliest formed a discharge commenced, and continued up to the time he came under Mr. Gould's care. On the middle of the upper surface of the glans was a sessile truncated horn of yellowish color, translucent, and of the size of a small marble. The penis was amputated, the inguinal glands removed, and the patient rapidly recovered. Microscopic sections of the horn prepared by Mr. L. Hudson, showed the usual epidermal structure, the cells being flattened, nucleated, and in regular superposed layers; no enlarged papillæ entered the base of the horn; the ulcer was epitheliomatous: the glands showed no secondary deposits. Reference was made to Sir Erasmus Wilson's collection of ninety cases of horns, of which five were on the penis, and to the later collection made by Lebert, of a hundred and nine cases from various sources, of which six were on the penis. Mr. Gould also mentioned other cases, and stated that his specimen was the fourteenth recorded case of horn on the penis. Some of the horns had reached a great size; in one recorded by Mr. Jewitt the horn was three inches and a half long, and three-quarter inch in diameter. In another recorded by Pick, the horn was two inches and a half long; in the case recorded by Mr. Gould, the patient was in the habit of paring the horn down. It had been shown that horns originated in three different ways: from the inferior or sebaceous cysts, which was the most frequent mode; from the matrix of nails; and from some change occurring in warts. Those on the glans penis belonged to the last group. Histologically they fell into two classes, the papillary and flat; the specimen shown was of the latter kind.

The Administration of Phosphorus in Rickets.

The administration of phosphorus and of phosphates in rickets has been recommended, on the ground that in the diseased

bones the earthy phosphates are greatly deficient, and that, introduced into the system, these substances will supply the deficiency. Phosphorus, as is well known from the researches of Wegner, when given to growing animals, renders the developing cancellous tissue of the bones denser than natural, more like the compact tissue; even in adult animals, a similar change takes place. These results are independent, as Wegner showed, of the presence of excess of phosphates, for they occur when phosphates are absent from the food. Although, therefore, the reason for the administration of phosphorus in rickets is well grounded, medical men hold very different opinions as to its utility in that disease. Some have given it with cod-liver oil; as in Kassowitz's phosphorized cod-liver oil, which contains 0.01 per cent. of phosphorus. The objection to this mode of administration is not only that the phosphorus tends to deposit on standing, and thus a variable and even dangerous dose may be given, but it is impossible to say how much benefit (if any) that ensues is due to the oil, and how much to the phosphorus. A better mode of administration has been devised by Hasterlik. Phosphorus (0.01 per cent.) is dissolved in bisulphide of carbon (0.25 per cent.), and one hundred parts of water added; one teaspoonful is given twice daily, constituting a dose of 0.0001 gramme in the day. The bisulphide of carbon not only acts as a solvent for the phosphorus, but has, according to Dujardin-Beaumetz, a beneficial effect in intestinal catarrh, and might thus be of service in the early stages of rickets. How far this preparation is beneficial in the disease has not yet been sufficiently ascertained.

Two Successful Cases of Removal of Enormous Cancerous Growths of the Superior Maxilla.

Dr. Leopold Servais, of Antwerp, read a paper on the above before the Medical Society of London. He discussed the anatomy of the parts concerned, and exhibited photographs of the patient before and after operation. The superior maxillary bones in both cases were involved to such an extent as to render their ablation necessary. He gave statistics of the frequency of the different varieties of tumors met with in this region. The first patient was a lad, aged 9, who was operated upon in October, 1883. The growth protruded from the mouth and measured 19 centimètres long and 23 centimètres in circumference. It was ulcerated in two places. The general health of the patient was good. The tumor, which had been growing for six years, was smooth, and of the consistence of india-rubber. Dr. Servais followed Ferguson's method of removing it piecemeal. The patient lost a good deal of blood; nevertheless, his recovery was very rapid, and so far there had been no recurrence. The second case was that of a young woman, in whom the growth had begun at 11 years of age, and had always been the seat of very severe pain. Removal had been attempted on several occasions by surgeons, but the hæmorrhage had been so severe as to oblige them to desist. Caustics had also been tried without success, and after ten years' growth the tumor was as large as an adult head. The operation took five hours, but the patient recovered in about three months.

The Treatment of the Early Stages of Syphilis.

The *Journal of Cutaneous Diseases* states that Dr. Lipp, of Berlin, believes that the present method of early treatment of syphilis is still inadequate. Some physicians believe in attacking the disease energetically from the very onset, while others put off treatment until constitutional symptoms show themselves. Some of the first category have recommended excision of the primary lesion and extirpation of the infiltrated glands—an operation not easily carried out in a great number of cases, and one in which successes are reported only from scattered cases. The customary method of treating the disease only after constitutional symptoms have appeared has brought forth no essentially favorable results. The antidote to the poison must be employed quickly and in the right place. The physician must know the exact quantity of the drug he wishes to introduce into the system, and herein lies the advantage of the subcutaneous method. Another advantage offered is the possibility of bringing the specific remedy at once into contact with the lymphatic glands and nodes, where, after the initial lesion, the syphilitic process has its seat.

Dr. Lipp does not hesitate to say that in the treatment of syphilis the subcutaneous method seems to him indispensable. No other method so quickly softens and reduces lymphatic swellings. He employs for injection the tannate of mercury, as this preparation has given the best results in his hands, and never increases the daily dose beyond one-third grain.

Effects of Syphilis on Pregnancy.

In a recent number of the *Gazette des Hôpitaux* the following interesting conclusions are advanced:

1. Syphilis has an influence on the pregnant state by adding a complication, and by bringing about usually a premature birth.

2. The stage of the disease has an important influence.

3. Out of eight pregnancies in syphilitic women diseased for one or more years, two children lived, but were weakly.

4. Out of twelve women infected in the first four months of gestation, all children were born dead.

5. Syphilis acquired from the fourth to the sixth month of pregnancy is also very dangerous for the fœtus, the half at least succumbing.

6. Syphilis acquired during the last three months of gestation gives a little over fifty per cent. of living children, and is less dangerous to the fœtus than is maternal syphilis before impregnation.

7. Out of thirty-three pregnancies in syphilitic women, eight resulted in the birth of living children. Three-quarters terminated in the death of the fœtus.

8. Syphilis may cause difficulties in labor and complications following it, but this is relatively rare.

9. To be efficacious, antisyphilitic treatment should be begun from the very commencement of pregnancy, and continued during the whole term. Treatment should be persistently carried out in these cases, to have an effect on subsequent pregnancies.

Arsenical Wall-Papers.

A writer in an English exchange mentions a simple test for arsenic in wall-papers. No apparatus is needed beyond an ordinary gas-jet, which is turned down to quite a pin-point, until the flame is wholly blue; when this has been done, a strip of the paper suspected to contain arsenic is cut one-sixteenth inch wide, and one or two inches long. Directly the edge of this paper is brought into contact with the outer edge of the gas-flame, a gray coloration, due to arsenic, will be seen in the flame (test No. 1). The paper is burned a little, and the fumes that are given off will be found to have a strong, garlic-like odor, due to the vapor of arsenic acid (test No. 2). Take the paper away from the flame, and look at the charred end—the carbon will be colored a bronze-red—this is copper reduced by the carbon (test No. 3); being now away from the flame in a fine state of division, the copper is slightly oxidized by the air, and on placing the charred end a second time not too far into the flame, the flame will now be colored green by copper (test No. 4). By this simple means it is possible to form an opinion, without apparatus and without leaving the room, as to whether any wall-paper contains arsenic, for copper arsenic is commonly used in preparing wall-paper. Tests 1 and 2 would be yielded by any paper containing arsenic in considerable quantities.

Test of Annatto in Butter.

Mr. H. B. Cornwall gives in the *Pharmaceutical Record* the following as a reliable means for discovering annatto in butter:

About 5 grams of the warm filtered fat are dissolved in about 50 c. cm. of ordinary ether, in a wide tube, and the solution is vigorously shaken for 10 to 15 seconds, with 12 to 15 c. cm. of a very dilute solution of caustic potash of soda in water, only alkaline enough to give a distinct reaction with turmeric paper, and to remain alkaline after separating from the ethereal fat solution. The corked tube is set aside, and in a few hours, at most, the greater part of the aqueous solution, now colored more or less yellow by the annatto, can be drawn from beneath the ether with a pipette, or by a stop-cock below, in a sufficiently clear state to be evaporated to dryness and tested in the usual way with a drop of concentrated sulphuric acid.

Sometimes it is well to further purify the aqueous solution by shaking it with some fresh ether before evaporating it, and any fat globules that may float on its surface during evaporation should be removed by touching them with a slip of filtered paper, but the solution should not be filtered, because the filter paper may retain much of the coloring matter.

The Infection of Wet-nurses by Syphilitic Sucklings.

Professor Fournier, of Paris, in a clinical lecture, recently gave the history of a case in which an apparently healthy wet-nurse became, a fortnight after commencing her duties, the subject of an ulceration on the nipple, subsequently recognized as syphilitic. This, in the meantime, was naturally communicated to the infant. On inquiry, no history of syphilis could be traced, either on the part of the nurse or the parents of the infected infant; but it was ascertained that the nurse had already suckled an infant

which had succumbed to symptoms of undoubted syphilis. At the time, therefore, that she accepted the second engagement she was already infected, but the disease was in the period of incubation. Dr. Fournier said he had met with fourteen cases of this description, and advised greater care in the selection of wet-nurses. Two precautions were specially indicated, namely, to engage no woman who had suckled any other than her own child; and if this were not practicable, to require a medical certificate of the last infant's immunity from contagious disease.

Some Notes on the Collapse of Cholera.

Mr. William Sedgwick recently directed the attention of the Harveian Society of London to the arrested formation of the chief constituents of urine and bile as the cause of the suppresion of those secretions during collapse. Attempts had been made to account for the absence of uræmic poisoning in cholera by what was known as the theory of vicarious secretion. Very little attention had been bestowed upon the absence of jaundice, although, in accordance with the theoretical opinion then entertained, there should be some tendency in cholera patients to become yellow or green, instead of simply blue. It had been suggested that the suppression of urine and bile was due to defective oxygenation of the blood. There was, however, no evidence from chemical analysis to support such a view; while the author had fully demonstrated that there was "an absolute reduction in the pulmonary interchange of gases, and, as the result of such reduction, an increase in the usual proportion of the oxygen absorbed." There was absolutely nothing in medical science to justify the retention of this theory of defective oxygenation; for it had been repeatedly disproved by chemical analysis, and it was physiologically unsound.

How to Administer Ergot.

A paper on "Ergot in Labor and Puerperal Convalescence" was recently read by Dr. T. A. Reamy, before the Cincinnati Academy of Medicine (says the *College and Clinical Record*), which embodied protests against the indiscriminate employment of this drug, and concluded with the following rules:

1. Ergot may properly be administered in small doses, say 10 to 20 drops of Squibb's fluid extract, before delivery, in cases of uterine inertia which resist other means, and especially in women who are predisposed to hemorrhage,

2. It should be administered in full doses hypodermatically, or *per orem*, or both, in cases of post-partum hemorrhage.

3. When an anæsthetic has been freely used during the second stage of labor, it to some degree predisposes to post-partum hemorrhage. Ergot is, therefore, indicated.

4. It should be administered in small doses, two or three times daily during the period of puerperal convalescence, whenever a flabby uterus indicates it. In such cases there is no better combination than the pill recommended by Munde: One grain of extract of ergot, one grain of quinine, and one-fourth of a grain of extract of nux vomica.

Compound Dislocation of the Ankle-Joint.

Dr. W. L. Rodman, of Louisville, Ky., recently read a paper on this subject (says the *College and Clinical Record*) before the Louisville Medical Society, in which he laid down the following general rules:

1. An extensive lacerated wound with comminution of bones, caused by direct crushing violence, as railway cars, etc., will require amputation as a rule.

2. Advanced age makes amputation probable; yet one of the very worst cases reported by Cooper was that of a butcher, seventy-three years old, and of intemperate habits, who recovered rapidly.

3. Where the tibia was dislocated externally it makes a more serious wound than when internally, causing more injury to bone and softer parts. For this reason amputation will be necessary in a greater number of these cases than in internal luxations.

4. If a large vessel be divided, and at the same time the soft parts badly lacerated, amputation may be necessary. It is *not imperatively demanded*, as most authors state.

5. Excessive suppuration, great irritability of constitution, gangrene, tetanus, deformity, all may call for amputation secondarily.

The Climatic Treatment of Tuberculosis.

In a discussion of the "Lessons Taught by the Climatic Treatment of Tuberculosis," instituted by a paper recently read before the Cincinnati Medical Society, by Dr. R. B. Davy (*Cincinnati Lancet-Clinic*, February 5, 1887), the following important deductions were made by the author:

1. Tuberculosis is an infectious disease.

2. The infection depends more on quantity than quality of virus.

3. On the open tropical sea, where every

condition favoring the development of tuberculosis is present except the presence of tubercular spores, the disease speedily disappears.

4. The nearest approach to perfect immunity from tuberculosis is to be found on high mountains, where, on account of extreme thinness and accompanying dryness of the air, the tubercular organism cannot exist.

Treatment of Fever.

At a recent meeting of the Paris Biological Society, M. Albert Robin gave further details of his researches on the subject of fevers. In typhoid more especially, medicaments should be employed which increase oxidation, such as oxygen, cold baths, cutaneous derivatives, chlorate of potash, iodates, and bromates. Substances like sulphate of quinine and antipyrin, which diminish oxidation, should be avoided. Chlorate of potash, iodates and bromates must be given very cautiously, owing to the poisonous effects of large doses. M. Robin thinks that they may be replaced by drugs which indirectly favor oxidation, such as alcohol, copious draughts of fluid milk, etc. M. D'Arsonval stated that the results obtained by the use of cold baths, as described by M. Robin, agreed with his own investigations on the temperature of animals. In animals, however, oxygen did not increase heat.

Pumpkin Seed in Tapeworm.

In the *New Orleans Medical Journal*, Dr. Veazie relates the case of a boy treated as follows for tapeworm:

A large pumpkin was bought and made into pies. The seeds were dried and hulled, and the pockets of the little fellow filled with them. Whenever he got hungry he was given a piece of pie, about all he ate in twenty-four hours. In addition, he was encouraged to eat the seed quite freely. For one day he tried seed and pie exclusively. At night he was given 15 grains of kamela. The next morning the first thing he said to his father was: "Papa, the worm is dead." At nine o'clock he passed the worm, head and all. Its total length was 30 feet, which, added to the pieces which had been passed before and carefully measured, made altogether 40 feet. The little fellow is in excellent health.

Treatment of Typhoid Fever.

Dr. Bampton opened a discussion on the treatment of typhoid fever, before an English medical society, advocating the use of quinine in considerable doses, and cold applications to combat hyperpyrexia, where the cold bath treatment was not practicable. The administration of antipyrin had, in his hands, been followed by marked lowering of temperature, accompanied by sweating, and followed by refreshing sleep. No untoward symptoms were observed. Malt extract was suggested as a valuable dietetic adjuvant. The cautious return to farinaceous food, after the normal temperature had been reached, was insisted upon. Cardiac exhaustion in the later stages of the fever was best treated with old sherry, or other highly etherized wines. A discussion followed, in which a large number of members and visitors joined.

Poisoning by Iodoform.

In some statistics of this accident collected by Dr. Willemen out of seventy-nine cases he found thirty-four or forty-three per cent. occurring in persons of fifty years or over, twenty-nine per cent. of them being between fifty and sixty, fifty per cent. between sixty and seventy, and twenty-one per cent. over seventy years of age. Fifty-three per cent. of those over fifty years of age died from the effects of the poisoning. In most cases, the symptoms appeared first in the second week. An earlier beginning denoted a severe case. Death took place once in the sixth week, twice in the third, and in the other fatal cases, on an average of seven or eight days from the first onset. The third day is considered an especially fatal one.

Acute Pneumonia in Utero.

Dr. Strachan, of Kingston, Jamaica,, writes as follows to the *Brit. Med. Journal*: A patient, Nancy M., was admitted into the hospital under my care in December last, suffering from acute pneumonia (whole of left lung), and a history of illness covering the four days previous to admission. She was eight months pregnant. On the evening of the day of admission, her temperature was 103.6°, and she was delivered of a female infant. The infant died in less than twenty-four hours after birth with symptoms of acute pneumonia. A post-mortem examination showed acute pneumonic consolidation of the whole of the left lung. The mother made a good and rapid recovery.

Perityphlitis followed by Hip-Joint Disease.

Before an English medical society, Dr. Brady related a case in which a young man

had a severe attack of perityphlitis, which went on to form an abscess. This was opened, and a plum-stone was found in the discharge. Three months after the commencement of the disease, the patient complained of severe pain in the hip-joint of the same side, with distressing jerking of the whole limb. On examination, the joint was found to be affected, and pus began to form in many directions around it. The joint disease was treated in the usual way, and fifteen abscesses in all were opened before ankylosis resulted. A year after the commencement of the disease, the patient was able to walk, with a firmly ankylosed joint.

Suppositories of Peptone.

The *Pharmaceutical Record* states that German apothecaries prepare these suppositories with cacao butter, each containing 25 grains of peptone; they are mixed and kept cold to prevent the fat from becoming rancid.

In cases where patients cannot be nourished in the normal manner, they serve an excellent purpose, 15 grains of dried peptone equalling 2½ drams of meat in nutritive value.

Children may be given one suppository four times daily; grown persons, two three times daily. The suppository should be lubricated with olive oil, and the rectum previously cleansed by an enema.

Chronic Lead Poisoning.

In the course of a discussion on this subject in the *Boston M. and S. Jour.*, Dr. Bowditch said that a case had come under his observation, where the only discoverable source of the lead was the solder used in kettles in which the water was boiled.

Dr. Wadsworth mentioned a case of simple optic atrophy occurring in a painter, in consequence of lead-poisoning. Except this lesion, there were almost no other symptoms pointing to this source. He had slight numbness of the hands and rheumatism of the left shoulder. The tendon reflex was not altered. Within a year he had seen a case of optic neuritis, with paralysis of the muscles, from lead.

Reindeer Tendon as a Substitute for Catgut.

Dried reindeer tendon was first recommended as a very cheap, but effective substitute for catgut by Dr. Putiloff, of Ormsk, in 1884. In the *Vratch*, No. 1, 1887, M. Kriedener, a veterinary surgeon practicing in the Trans-Petchora District, which is the home of the reindeer, writes that he has also used this material in several cases of operations upon animals with most satifactory results. He is prepared to send specimens of the ligature in question, free of cost, to any surgeon who may be enterprising enough to write to him at the following address: Mokhtchenskaia, Potchtovaia Stantzia, Mezensky Uiezd, Arkhangelsk Government, Russia.

Treatment of Diabetes.

Dr. Austin Flint, of New York, has reported the details of 88 cases of diabetes. A study of the progress of these cases confirms the belief that, in uncomplicated cases, of not more than twelve months' standing, careful dietetic treatment, which usually is well borne, will always produce great improvement, will generally eliminate sugar from the urine, and will completely restore the general health, although relapses are very liable to occur if a moderate anti-diabetic diet be not continued for an indefinite period. Very little reliance is to be placed upon the use of drugs.

Entozoa and Pernicious Anæmia.

Dr. G. Reyher, writing on the etiology of pernicious anæmia (*Lancet*, January 29, 1887), points out that, in a large number of these cases a Bothriocephalus latus has been diagnosed and expelled by means of male fern, the patients subsequently recovering, and as the anæmia of miners is now known to be due to the Anchylostomum duodenale, it is possible that all cases are due to entozoa of one kind or another, and that therefore diligent search should always be made in the fæces for the ova of tæniæ, etc. The treatment will in cases of successful search be obvious.

Ectopia Vesicæ.

Before an English medical society, Mr. Shattock showed a specimen of ectopia vesicæ in a male child, and made some observations on the anatomy of the malformation. He suggested that the condition might be explained by supposing that the primitive cloacal invagination, by undue extension upwards, laid open the anterior wall of the urino-genital sinus and the bladder. In confirmation of this view, he mentioned that epispadias occurred without ectopia, but not ectopia without epispadias.

Chronic Dysentery.

For chronic dysentery, with a great deal of pain, Prof. Da Costa directed as follows:

Allow only a mild diet, mostly of milk, but he may take oysters in small amounts, the milk to be diluted with lime-water. Give a one-grain suppository of extract of opium at night, to be repeated if pain persists. Also—

℞.	Btsmuthi subnitratis,	gr. xv.
	Pulv. ipecac. et opii,	gr. ij.
	Pulv. aromat.,	gr. ij.

M. Sig.—Take every third hour.

The Blood in Leukæmia.

According to Dr. Prus (*Medycyna*, No. 39, 1886, and *St. Petersburg Med. Wochenschrift*, No. 1, 1887, p. 1), who bases his statements on five cases of his own, leucin-crystals are met with only in those cases of leukæmia in which the lymphatic glands are diseased. The number of Bizzozero's corpuscles is, as a rule, very considerable, while Charcot-Neumann crystals are very seldom found. Karyokynesis of leucocytes is always largely increased.

Rhino-lithiasis and Lupus of the Nose.

At a recent meeting of the St. Petersburg Medical Society, Dr. Lavr. V. Silitch showed (*Vratch*, No. 1, 1887, p. 16) calculi which he had removed from the nasal cavity of two patients suffering from lupus of the the nose, with offensive discharge in the one case of four, and in the other of two years' duration. In one of the stones, the nucleus consisted of a piece of dead bone.

Treatment of Diabetic Thirst.

Duchenne recommends (*Nouveaux Remédes*) the following mixture for the excessive thirst of diabetic patients:

℞.	Phosphate of potassium,	2 parts.
	Water,	75 parts.

One teaspoonful should be given two or three times a day in a little wine or hop tea.

News and Miscellany.

Small-pox Inoculation.

In a lecture recently delivered at St. Mary's Hospital, London (says the *Lancet*), Mr. Shirley Murphy adduced some evidence to show that there was a probability that the virus of small-pox obtained from the initial vesicle produced by inoculation of small-pox differed in its action from that obtained from the general eruption; and he expressed the opinion that it was probable the different results attending the operation of inoculation by various operators might be dependent upon the use of virus procured from the one or the other source. Thus of 182 inoculations performed in the years 1721 and 1722, three persons died, or nearly one in sixty; and in Dublin, in 1723, of twenty-three persons inoculated, three died. The not infrequent death from inoculated small-pox led at first to much opposition to this method of protection against natural small-pox, but later it was found that inoculation could be performed without risk.

In an account given by Sir George Baker of the extraordinary success attending the inoculations of Daniel Sutton, of Ingatestone, in Essex, who in three years inoculated some 20,000 persons without bad result, he attributed this success to the fact that Sutton allowed his patients to enjoy fresh air during their illness; while Dr. Glass, of Glasgow, believed that Sutton's treatment in encouraging perspiration was responsible for their recovery. It is clear that Sutton professed to have a secret in his treatment, although this secret is only mentioned in relation to the composition of certain medicine; but Sir George Baker, curiously enough, observed that "What is extremely remarkable, he (Sutton) frequently inoculates people with the moisture taken from the arm before the eruption of small-pox;" and Dr. Chandler, who also witnessed Sutton's work, referred the chief benefit of his plan to the infecting humor being taken in a crude state "before it has been ultimately variolated by the succeeding fever." Baron Dimsdale, who took much interest in Sutton's proceedings, and subsequently himself practiced inoculation, closely imitated his method, and was very successful in his results. If, as Mr. Murphy pointed out, the virus of the initial vesicle differs in any respect from that of the general eruption, some difference may also be found in the ease with which the bovine animal is inoculated with the one and the other virus. Certainly this point deserves further investigation.

Caring for the Insane.

The Berks County Medical Society has notified the Lunacy Committee of the Board of Public Charities of the appointment of Drs. W. Murray Weidman, Martin Luther and Rudolph B. Schulze, all of Reading as a Board of Visitors for the Insane.

This is the twenty-sixth County Medical Society which has appointed such a Board.

The others have not been heard from. The idea was suggested at the annual convention of the State Medical Society at Wilkesbarre last June, when a resolution was adopted requesting the various County Societies to appoint visitors, with authority to inquire into the condition of the insane in the almshouses and hospitals in the respective counties. The State Committee on Lunacy then agreed to authorize such Boards to visit the various institutions, and requested that they act in conjunction with the Committee. The suggestion was received with favor, but owing to the absence of many of the leading members of the various County Societies throughout the State, nothing was done until near the close of the year. The County Societies then got down to work, and in the course of three weeks twenty-six of them appointed visitors, and so notified the Lunacy Committee. Some of these Societies appointed as many as seven of their number, but most of them appointed only three.

The Jews of the World.

The *Hebrew Annual* says that France contains 63,000 Jews; Germany, 562,000, of whom 39,000 inhabit Alsace and Lorraine; Austria-Hungary, 1,644,000, of whom 688,000 are in Galicia and 638,000 in Hungary proper; Italy, 40,000; Netherlands, 82,000; Roumania, 265,000; Russia, 2,552,000 (Russian Poland, 768,000); Turkey, 105,000; Belgium, 3,000; Bulgaria, 10,000; Switzerland, 7,000; Denmark, 4,000; Spain, 1,900; Gibraltar, 1,500; Greece, 3,000; Servia, 3,500; Sweden, 3,000. In Asia there are 300,000 of the race; Turkey in Asia has 195,000, of whom 25,000 are in Palestine, 47,000 are in Russian Asia, 18,000 in Persia, 14,000 in Central Asia, 1,900 in India, and 1,900 in China. In Africa, 8,000 Jews live in Egypt, 55,000 in Tunisia, 35,000 in Algeria, 60,000 in Morocco, 6,000 in the Tripolitan, and 200,000 in Abyssinia. America counts 230,000 among her citizens, and 20,000 more are distributed in other sections of the trans-Atlantic continents, while only 12,000 are scattered through Oceanica. In short, the entire total of the Hebrew race on the surface of the globe is 6,300,000.

Are They the Lost Tribes?

A correspondent, signing himself W. Tully, thus writes to the *Philadelphia Times:*

Having been for many years on our far Western frontiers, and being a close observer of the customs of the Indian tribes, I am convinced that they are the lost tribes of Israel. In the first place, they believe in a Great Spirit and a happy hunting ground, corresponding to the Christian's God and heaven.

Second. They will not eat the flesh of the hog under any consideration. Having been through various tribes, it was the same.

Third. When an Indian is thirsty and comes to a stream of any drinking water he will not kneel down like a white man, but will squat down, form a sort of scoop out of his hand, throw the water into his mouth in a continual stream, until his thirst is appeased. Now, if we take a glance into the Book of Gideon we will find that when he marched to attack the Philistines that when he arrived at a certain brook all the men who knelt down were to be left behind and that those who lapped water by hand were to be selected. It appears from that account that there were three hundred, with which small number he smote the Philistine host and gained the victory.

Fourth. The Indians in their features bear a striking resemblance to the Jews.

Paris Hospitals a Century Ago.

The celebrated Hôtel Dieu, in Paris, only about one hundred years ago presented many features consistent neither with humanity nor the most rudimentary hygiene, as we understand the subject. A humane law forbade the hospital to turn away any patient seeking admission; but the law, apparently, did not insist upon the provision of the necessary space. The whole establishment covered only about three acres, and within this area there were crowded at one time over five thousand sick and injured people. It was computed that, without allowing anything for staircases, passages, and offices of various kinds, there must have been a sick person in every floor space of thirty square feet, right throughout the hospital—every floor space seven feet and a half long and four feet wide, that is to say. A large proportion of the beds were intended to hold four people, and into these six patients were frequently crowded. It is said to have been no unusual thing for two or three small-pox patients to have been huddled into a single bed, and as many as four women in childbirth were thus laid side by side. Indeed, if some accounts may be relied upon, things were at times far worse than this. The hospital seems to have been adapted only for times of normal public health. Any outbreak of epidemic disease crowded the place to a frightful extent.

Photo-micrographs of Butter and Fat.

Bernard Persh, hospital steward at the Frankford Arsenal, Philadelphia, has made a series of beautiful photographs, showing (under powers of 80 to 140 diameters and polarized light) oleomargarine, oleo, lard, marrow fat, beef fat, butter, and Taylor's "secondary butter crystals." In the photographs very marked differences appear between the various fats.

The importance of this subject is not to be under-estimated. The extent to which the manufacture of oleomargarine is carried on in the United States may be judged from the fact that the tax from this source alone for the month of November was estimated by Treasury officials to amount to $400,000. (All oleomargarine and butterine now sold must pay a tax of two cents per pound, and must be plainly designated to distinguish it from butter.)

Beecher's Voice in the Phonograph.

In the house of Thomas A. Edison, at Llewellyn Park, is a remarkable memento of Beecher. The inventor's phonograph for impressing on a soft metal sheet the utterances of the human voice, and then emitting it again by the turning of a crank has never been put to any very valuable use, and Edison has only gathered from it a few thousand dollars in royalties from exhibitors. But he utilized it to make a collection of famous voices. Since he became famous his visitors have included hundreds of celebrities. Instead of asking them for their autographs or photographs, he has in two or three hundred instances requested them to speak a few sentences into a phonograph. He has kept the plates in a cabinet, and occasionally he runs some of them through the machine, which sends out the words exactly as uttered. Edison is probably the only man who can revive the silenced voice of the great preacher.

In Memory of Arctic Surgeon Ambler.

The memory of the late Dr. James Markham Ambler, surgeon of the ill-starred Jeannette, who died in the Arctic regions, has been honored by the hanging of a bronze tablet five feet long by three and a half wide, in the Corcoran Art Gallery at Washington. The design is a classic one, with a medallion portrait of the subject on its face. Below this is a representation of a scene on the banks of the Lena Delta, in which Dr. Ambler is represented as performing his duties toward the sick members of the party, while waving his hand in farewell to the two men who are leaving in search of help, after a vain attempt to persuade him to accompany them. The inscription gives the subject's name and date of death, and closes with the words, "Duty stronger than love of life."

Diploma Mill in Maine.

The *Boston Herald* has recently ventilated an extensive diploma industry in Lewiston, Me., a representative of that paper, who says that he is innocent of any knowledge of medicine, having obtained without difficulty a diploma from the Maine Branch of the "Druidic University of America." As this "Branch" is incorporated under the State law, the people of the State must now pay the expenses of "a joint special committee" from the House and a few Senators, "to inquire into the expediency of repealing" the character of the Maine Branch and the Maine Eclectic Medical College.

A Strange Malady in a Delaware Town.

News comes from Lewes, Del., that a malady has stricken the town, and that it was all brought about by a very lively old-fashioned meeting in the Methodist church. People became very warm and excited in the crowded, ill-ventilated church, and when they left for their homes many took severe colds. It is said that "dry measles" followed in a most virulent form, and that over 100 cases are reported. It is also claimed that five persons have died from the strangely-contracted malady.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE FIVE WEEKS ENDED MARCH 5, 1887.

Guiteras, John, passed assistant surgeon. Granted leave of absence for twenty-one days, February 28, 1887.

Pettus, W. J., assistant surgeon. To proceed to Charleston, S. C., for temporary duty, February 28, 1887.

A Fund Left to Harvard College for Astronomical Research.

The President and Fellows of Harvard College have recently come into possession of a munificent bequest of $230,000 and upwards, which is applicable only for purposes of special astronomical investigation, at such an elevation as to be free, so far as practica-

ble, from the impediments to accurate observations which occur in observatories now existing owing to atmospheric influence.

A New Explosive for Russia.

The experiments with a new explosive, which have been made under the supervision of the government, have been attended with great success. The explosive possesses fifteen times greater destructive power than gunpowder. It does not produce any smoke.

Personals.

—Dr. Marcy, of Camden, writes from St. Augustine, Florida, that he is rapidly regaining his health.

—Dr. T. Hollingsworth Andrews will direct the arrangements for the dinner of the Alumni Association of the Jefferson Medical College, which takes place on Monday, April 4th.

—Dr. J. Ewing Mears delivered the recent annual address before the Philadelphia Academy of Surgery.

Items.

—A citizen of Durand, Wis., scooting down on his toboggan, ran into a cow and knocked her legs out from under her, and she sat down on him and crushed him nearly as flat as his toboggan.

—A fourteen-year-old scholar in the district school near Vandalia, Ill., took a swallow from his ink bottle the other day to see how it would taste. The next morning he died. His physician said that the ink contained a deadly poison.

—"And now," concluded the revivalist, "if there is any one here who wants to ask any question, let him be heard." "I'd like to know," said a bald-headed sinner, rising in the back seat, "how many marbles have been dropped on my head by those scalawags in the gallery. I'm no pavement."

—A bad boy in a Massachusetts village surprised and pleased his teacher by promising to contribute a fine steel engraving of Washington to aid in decorating the schoolroom on February 22. The teacher left a large space among the evergreen trimmings on the wall, and the boy brought her a two-cent postage stamp.

—A test for oleomargarine has been sound. It is as follows: Take the sample of supposed butter to be tested, and if you find a red hair as long as your arm, you may be satisfied that a woman made it, and that it is genuine butter, as oleomargarine is manufactured exclusively by short-haired or bald-headed men.

"The Hymen in Mexico" is the rather sensational title of a recently-published work. The author states that the complete absence of the hymen in Mexican virgins is very rare. Apart from this, however, the book contains no startling items of information, but treats of the subject chiefly from a medico-legal point of view.

—A prize of 50,000 francs is offered by the French Minister of Education for a discovery rendering electricity economically applicable in the shape of heat, light, chemical action, mechanical power, transmission of messages, or treatment of disease. M. Bertrand, of the Académie des Sciences, is chairman of the committee of award.

—Has quinine ever killed anybody? It would be interesting to learn of a case of serious danger resulting from an overdose, for quinine substitutes are now and again causing unanticipated results. A practitioner in Lausanne had a phthisical patient under his charge, who died from swallowing half a bottleful of a mixture which contained 24 grains of antipyrin; and another had a patient who became comatose, and so remained for three days, after taking 3 grammes of the remedy.

OBITUARY NOTICE.

James Porter Peck, M. D.
